Golden Ratio in the Point Sink Induced Consolidation Settlement of a Poroelastic Half Space

Feng-Tsai Lin¹ and John C.-C. Lu²

¹Department of Naval Architecture, National Kaohsiung Marine University
²Department of Civil Engineering & Engineering Informatics, Chung Hua University
Taiwan

1. Introduction

The golden ratio \( \phi \) has been well known in mathematics, science, biology, art, architecture, nature and beyond (Sen & Agarwal, 2008), which is the irrational algebraic number \( \left(1 + \sqrt{5}\right)/2 \approx 1.618033989 \). It’s interesting to find that the golden ratio exists in the point sink induced consolidation settlement of a homogeneous isotropic poroelastic half space. Examples of the golden ratio in engineering include the study of shear flow in porous half space (Puri & Jordan, 2006) and classical mechanics of coupled-oscillator problem (Moorman & Goff, 2007).

Land subsidence due to groundwater withdrawal is a well-known phenomenon (Poland, 1984). The pore water pressure is reduced in the withdrawal region when an aquifer pumps groundwater. It leads to increase in effective stress between the soil particles and subsidence of ground surface.

The three-dimensional consolidation theory presented by Biot (1941, 1955) is generally regarded as the fundamental theory for modeling land subsidence. Based on Biot’s theory, Booker and Carter (1986a, 1986b, 1987a, 1987b), Kanok-Nukulchai and Chau (1990), Tarn and Lu (1991) presented solutions of subsidence by a point sink embedded in saturated elastic half space at a constant rate. In the studies of Booker and Carter (1986a, 1986b, 1987a, 1987b), the flow properties are considered as isotropic or cross-anisotropic whereas the elastic properties of the soil are treated as isotropic with pervious half space boundary. Tarn and Lu (1991) found that groundwater withdrawal from an impervious half space induces a larger amount of consolidation settlement than from a pervious one. Chen (2002, 2005) presented analytical solutions for the steady-state response of displacements and stresses in a half space subjected to a point sink. Lu and Lin (2006) displayed transient ground surface displacement produced by a point heat source/sink through analog quantities between poroelasticity and thermoelasticity. Hou et al. (2005) found that pumping induced ground horizontal velocities range from 31 to 54 mm/yr towards azimuths 247° to 273° in the Pingtung Plain of Taiwan. Their results show that ground horizontal displacement occurred...
when pumping from an aquifer. Nevertheless, the consolidation settlement due to pumping were not thoroughly discussed in the above theoretical studies. The aquifer is modeled as an isotropic saturated pervious elastic half space in this analytical research. Using Laplace and Hankel integral transform techniques, the transient horizontal and vertical displacements of the ground surface due to a point sink are obtained. The study also focused on the distributions of excess pore water pressure of the half space on the consolidation history. Results are illustrated and compared to display the time dependent consolidation settlement due to pumping.

2. The Golden Ratio

The golden ratio $\phi$ can be derived from a geometrical line segment in extreme and mean ratio as shown in Figure 1, where the ratio of the full length 1 to the length of $x$ is equal to the ratio of section part $x$ to shorter section $1 - x$:

$$\frac{1}{x} = \frac{x}{1-x}.$$  \hfill (1)

Assuming, $x = 1/\phi$, hence, $\phi$ satisfies

$$\phi^2 - \phi - 1 = 0.$$  \hfill (2)

The golden ratio is the positive root of Eq. (2):

$$\phi = \frac{1 + \sqrt{5}}{2}.$$  \hfill (3)

Fig. 1. Dividing the unit interval according to the golden ratio

Fig. 2. The golden rectangle
Golden Ratio in the Point Sink Induced Consolidation Settlement of a Poroelastic Half Space

when pumping from an aquifer. Nevertheless, the consolidation settlement due to pumping were not thoroughly discussed in the above theoretical studies. The aquifer is modeled as an isotropic saturated pervious elastic half space in this analytical research. Using Laplace and Hankel integral transform techniques, the transient horizontal and vertical displacements of the ground surface due to a point sink are obtained. The study also focused on the distributions of excess pore water pressure of the half space on the consolidation history. Results are illustrated and compared to display the time dependent consolidation settlement due to pumping.

2. The Golden Ratio

The golden ratio \( \phi \) can be derived from a geometrical line segment in extreme and mean ratio as shown in Figure 1, where the ratio of the full length 1 to the length of \( x \) is equal to the ratio of section part \( x \) to shorter section \( 1 - x \):

\[
\frac{1}{x} = \frac{x}{1-x}.
\] (1)

Assuming, \( 1/x = \phi \), hence, \( \phi \) satisfies

\[
2\phi - \phi^2 = 1.
\] (2)

The golden ratio is the positive root of Eq. (2):

\[
\phi = \frac{1 + \sqrt{5}}{2}. \quad (3)
\]

Figure 2 displayed another geometric description of golden ratio through the golden rectangle. Giving a rectangle with sides’ ratio \( a : b \), the removing of square section leaves the remaining rectangle with the same ratio as original rectangle, i.e.,

\[
\frac{b}{a-b} = \frac{a}{b}. \quad (4)
\]

Thus, this solution is the golden ratio \( \phi \):

\[
\phi = \frac{a}{b} = \frac{1 + \sqrt{5}}{2}. \quad (5)
\]

The golden ratio is a remarkable number that arises in various areas of mathematics, natures and arts. There are many interesting mathematical properties of \( \phi \). For example, \( \phi \) can be expressed as a continuous fraction with the single number 1 (Livio, 2002):

\[
\phi = 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \ldots}}}. \quad (6)
\]

Also, the golden ratio \( \phi \) can be expressed as a continuous square root of the number 1:

\[
\phi = \sqrt{1 + \sqrt{1 + \sqrt{1 + \ldots}}}. \quad (7)
\]

www.intechopen.com
However, the most interesting is that $\phi$ is within Fibonacci series (Livio, 2002; Dunlap, 1997). The Fibonacci series is a set of numbers that begins with two 1s and each term therefore is the sum of the prior two terms, i.e., 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, \ldots. The relationship between two successive numbers of Fibonacci series tends to approach $\phi$ as shown in Table 1.

Based on Biot’s (1941, 1955) three-dimensional consolidation theory of porous media, this study modeled the saturated aquifer as a homogeneous isotropic poroelastic half space. Closed-form solutions of the transient and long-term consolidation deformations and excess pore water pressures due to a point sink are presented in this paper. It’s interesting to find that the golden ratio $\phi$ appears in the point sink induced maximum ground surface horizontal displacement and corresponding settlement of a poroelastic half space.

3. Mathematical Models

3.1 Basic Equations

Figure 3 presents a point sink buried in a saturated porous elastic aquifer at a depth $h$. The aquifer is considered as a homogeneous isotropic porous medium with a vertical axis of symmetry. Assuming the model is decoupled, i.e., the flow field is independent from the displacement field. Considering a point sink of constant strength $Q$ located at point $(0,h)$, the basic governing equations of the elastic saturated aquifer for linear axially symmetric deformation can be expressed in terms of displacements $u_r$ and excess pore water pressure $p$ in the cylindrical coordinates $(r, \theta, z)$ as follows (Lu & Lin, 2006, 2008):

\[
G \nabla^2 u_r + \frac{G}{1-2\nu} \frac{\partial \varepsilon}{\partial r} - G \frac{u_r}{r^2} - \frac{\partial p}{\partial r} = 0, \tag{8a}
\]

\[
G \nabla^2 u_z + \frac{G}{1-2\nu} \frac{\partial \varepsilon}{\partial z} - \frac{\partial p}{\partial z} = 0, \tag{8b}
\]

\[
-\frac{k}{\gamma} \nabla^2 p + n \beta \frac{\partial p}{\partial t} + \frac{Q}{2\pi r} \delta(r) \delta(z-h) u(t) = 0, \tag{8c}
\]

where $\nabla^2 = \partial^2 / \partial r^2 + 1/r \partial / \partial r + \partial^2 / \partial z^2$ is the Laplacian operator. The excess pore fluid pressure $p$ is positive for compression. The displacements $u_r$ and $u_z$ are in the radial and axial directions, and $\varepsilon = \tilde{\varepsilon} r / \partial r + u_r / r + \tilde{\varepsilon} / \partial z$ is the volume strain of the porous medium. The quantities $\nu$, $G$, $k$, $n$, $\gamma$, and $\beta$ denote the saturated aquifer’s Poisson’s ratio, shear modulus, aquifer permeability, porosity, pore water unit weight and compressibility, respectively. The functions $\delta(x)$ and $u(t)$ are Dirac delta and Heaviside unit step function, respectively.
The relationship between two successive numbers of Fibonacci series tends to approach
where

3.2 Boundary Conditions
The saturated aquifer is considered as a homogeneous isotropic half space and the
consitutive behavior of the aquifer can be expressed by the total stress components
\[ \tau_j = \frac{2G\nu}{1-2\nu} \varepsilon_j + 2G\varepsilon_j - p\delta_j, \]
where \( \varepsilon_j = \frac{\partial u_j}{\partial r} \), \( \varepsilon_0 = \frac{u}{r} \), and \( \varepsilon = \frac{\partial u}{\partial z} \), respectively; and \( \delta_0 \) is the
Kronecker delta. In this paper, the half space surface, \( z = 0 \), is considered as a traction-free
pervious boundary for time \( t \geq 0 \). From the constitutive relationships shown above, the
mechanical boundary conditions at \( z = 0 \) are expressed in terms of \( u \) and \( u_t \) by

\[ \frac{2G\nu}{1-2\nu} \left[ \frac{\partial u_t(r,0,t)}{\partial r} + \frac{u_t(r,0,t)}{r} \right] + \frac{G(1-\nu)}{1-2\nu} \frac{\partial u_t(r,0,t)}{\partial z} = 0, \]  
(9a)

\[ G \left[ \frac{\partial u_t(r,0,t)}{\partial z} + \frac{\partial u_t(r,0,t)}{\partial r} \right] = 0. \]  
(9b)

An additional condition is provided by considering the half space as pervious and the
mathematical statement of the flow condition at the boundary \( z = 0 \) is given by

\[ p(r,0,t) = 0. \]  
(9c)

The boundary conditions at \( z \to \infty \) due to the effect of the point sink vanish when \( t \geq 0 \).

3.3 Initial Conditions
Assuming no initial changes in displacements and seepage of the aquifer, the initial
conditions of the mathematical model at time \( t = 0 \) are

\[ u(r,z,0) = 0, \quad u_t(r,z,0) = 0, \quad \text{and} \quad p(r,z,0) = 0. \]  
(10)
4. Analytic Solutions

4.1 Laplace and Hankel Transforms Solutions

The governing partial differential equations (8a)-(8c) are reduced to ordinary differential equations by performing Laplace and Hankel transforms (Sneddon, 1951) with respect to the time variable \( t \) and the radial coordinate \( r \):

\[
\left( \frac{d^2}{dz^2} - 2\eta \xi^2 \right) \tilde{u} + \left( 2\eta - 1 \right) \xi \frac{du}{dz} + \frac{1}{G} \xi \tilde{p} = 0 ,
\]

\[
(2\eta - 1) \xi \frac{d\tilde{u}}{dz} + \left( 2\eta \frac{d^2}{dz^2} - \xi^2 \right) \tilde{u} - \frac{1}{G} \frac{d\tilde{p}}{dz} = 0 ,
\]

\[
-\frac{k}{\eta} \left( \frac{d^2}{dz^2} - \xi^2 \right) \tilde{p} + n \beta s \tilde{p} + \frac{Q}{2\pi s} \delta(z - h) = 0 ,
\]

where \( \xi \) and \( s \) are Hankel and Laplace transform parameters. The parameter \( \eta = (1 - \nu)/(1 - 2\nu) \) and the symbols \( \tilde{u}, \tilde{u}, \tilde{p} \) are defined as

\[
\tilde{u}(z; \xi, s) = \int_0^\infty rL[u(r, z, t)] J_\nu(\xi r) \, dr ,
\]

\[
\tilde{u}_r(z; \xi, s) = \int_0^\infty rL[u_r(r, z, t)] J_\nu(\xi r) \, dr ,
\]

\[
\tilde{p}(z; \xi, s) = \int_0^\infty rL[p(r, z, t)] J_\nu(\xi r) \, dr ,
\]

in which \( J_\nu(x) \) represents the first kind of Bessel function of order \( \nu \). The Laplace transforms in equations (12a)-(12c) with respect to \( u_r, u_z, p \) are denoted by

\[
L[u_r(r, z, t)] = \int_0^\infty u_r(r, z, t) \exp(-st) \, dt ,
\]

\[
L[u_z(r, z, t)] = \int_0^\infty u_z(r, z, t) \exp(-st) \, dt ,
\]

\[
L[p(r, z, t)] = \int_0^\infty p(r, z, t) \exp(-st) \, dt .
\]

The general solutions of equations (11a)-(11c) are obtained as

\[
\tilde{u}(z; \xi, s) = C_1 \exp(\xi z) + C_2 z \exp(\xi z) + C_3 \exp(-\xi z) + C_4 z \exp(-\xi z)
\]

\[
+ C_5 \exp\left( \frac{\xi^2 + s^2}{c} \right) + C_6 \exp\left( -\frac{\xi^2 + s^2}{c} \right)
\]
4. Analytic Solutions

4.1 Laplace and Hankel Transforms Solutions

The governing partial differential equations (8a)-(8c) are reduced to ordinary differential equations by performing Laplace and Hankel transforms (Sneddon, 1951) with respect to the variables \( \xi \) and \( \theta \), and the symbols

\[
\begin{align*}
\varphi & = \left( C_1 + \frac{2\eta + 1}{2\eta - 1} C_3 \right) \exp(\xi z) - C_2 \exp(\xi z) + \left( C_4 + \frac{2\eta + 1}{2\eta - 1} C_5 \right) \exp(-\xi z) + C_6 \exp(-\xi z) \\
\end{align*}
\]

where \( C_1 \) and \( C_6 \) are determined from the transformed boundary conditions. The upper and lower signs in Eq. (14b) are for the conditions of \( z - h \geq 0 \) and \( z - h < 0 \), respectively.

4.2 Transformed Boundary Conditions

Taking Hankel and Laplace transforms for Eqs. (9a)-(9c), the mechanical and flow boundary conditions at \( z = 0 \) of the transformed domains are derived as follows:

\[
\frac{d\tilde{u}}{dz} (0; \xi, s) + (\eta - 1)\xi \tilde{u} (0; \xi, s) = 0, \quad \frac{d\tilde{u}}{dz} (0; \xi, s) - \xi \tilde{u} (0; \xi, s) = 0, \quad \tilde{p}(0; \xi, s) = 0,
\]

where \( \tilde{u} \), \( \tilde{\varphi} \), and \( \tilde{p} \) follow the definitions in Eqs. (12a)-(12c).

The constants \( C \) of the general solutions are determined by the transformed half space boundary conditions at \( z = 0 \) and \( z \rightarrow \infty \). Finally, the desired quantities \( u, \varphi, \) and \( p \) are obtained by applying appropriate inverse Hankel and Laplace transformations (Erdelyi, et al., 1954).

4.3 Expressions for Ground Surface Displacements

The focus of the study is on horizontal and vertical displacements of the ground surface, \( z = 0 \), due to a point sink. The transformed ground surface displacements are derived from Eqs. (14a)-(14b) with the help of transformed boundary conditions and they are obtained as follows:
\begin{align*}
\tilde{u}(0, \xi, s) &= \frac{Q\gamma}{2\pi(2\eta - 1)Gk} \left[ \frac{c}{s' \sqrt{s' + h}} \exp(-\xi h) + \frac{c}{s' \sqrt{s' + h}} \exp\left(\frac{-1}{\sqrt{s' + \frac{h}{c}}}\right) \right], \quad (16a) \\
\tilde{u}(0, \xi, s) &= \frac{Q\gamma}{2\pi(2\eta - 1)Gk} \left[ \frac{c}{s' \sqrt{s' + h}} \exp(-\xi h) - \frac{c}{s' \sqrt{s' + h}} \exp\left(\frac{-1}{\sqrt{s' + \frac{h}{c}}}\right) \right]. \quad (16b)
\end{align*}

Applying the Hankel inversion formulae lead to the following displacements:

\begin{align*}
&u_r(r, z, t) = \int_0^\infty \xi L^1\{\tilde{u}(z; \xi, s)\} J_1(\xi r) d\xi, \quad (17a) \\
&u_z(r, z, t) = \int_0^\infty \xi L^1\{\tilde{u}(z; \xi, s)\} J_1(\xi r) d\xi, \quad (17b)
\end{align*}

in which the Laplace inversions are defined as

\begin{align*}
L^1\{\tilde{u}(z; \xi, s)\} &= \frac{1}{2\pi i} \int_{-\infty}^{\infty} \tilde{u}(z; \xi, s) \exp(st) ds, \quad (18a) \\
L^1\{\tilde{u}(z; \xi, s)\} &= \frac{1}{2\pi i} \int_{-\infty}^{\infty} \tilde{u}(z; \xi, s) \exp(st) ds. \quad (18b)
\end{align*}

Using Eqs. (17a)-(17b) and (18a)-(18b), the transient horizontal displacement $u_r(r, 0, t)$ and vertical settlement $u_z(r, 0, t)$ of the pervious ground surface due to a point sink are obtained as follows:

\begin{align*}
u(r, 0, t) &= \frac{Q\gamma}{2(2\eta - 1)\pi Gk} \left[ \frac{ctr}{(h' + r')^3} \right. \\
&\quad + \int_0^t \frac{(ct - \tau)hr}{16r'} \exp\left(\frac{r' + 2h'}{8\tau}\right) \left[ L_1\left(\frac{r'}{8\tau}\right) - L_1\left(\frac{r'}{8\tau}\right) \right] d\tau \bigg], \quad (19a) \\
u_z(r, 0, t) &= \frac{Q\gamma}{2(2\eta - 1)\pi Gk} \left[ \frac{ctr}{(h' + r')^3} \right. \\
&\quad + \frac{h}{2\sqrt{h' + r'}} \exp\left(\frac{\sqrt{h' + r'}}{2\sqrt{ct}}\right) \left[ L_1\left(\frac{\sqrt{h' + r'}}{2\sqrt{ct}}\right) - L_1\left(\frac{\sqrt{h' + r'}}{2\sqrt{ct}}\right) \right] \bigg], \quad (19b)
\end{align*}

where $\text{erf}(x)$ and $\text{erfc}(x)$ are error function and complementary error function, respectively; and $L_1(x)$ is known as the modified Bessel function of the first kind of order $\nu$. The long-term ground surface horizontal and vertical displacements are obtained when $t \to \infty$:

4.4 Expression for Excess Pore Water Pressure

The study also addressed the excess pore water pressure of the porous elastic half space due to a point sink. The transformed excess pore water pressure is obtained from Eq. (14c) with the help of transformed flow boundary conditions, and it can be expressed as following:

\[
p(\xi; \zeta, s) = \frac{Qr}{4\pi k} \left\{ \frac{1}{s} \frac{1}{\sqrt{\xi^2 + \frac{z}{c}}} \exp \left[ -\sqrt{\frac{\xi^2}{\zeta} + \frac{z}{c}} (z + h) \right] - \frac{1}{s} \frac{1}{\sqrt{\xi^2 + \frac{z}{c}}} \exp \left[ -\sqrt{\frac{\xi^2}{\zeta} + \frac{z}{c}} (z - h) \right] \right\} . \tag{24}
\]

The Hankel inversion formula is applied as:

\[
p(r, z, t) = \int_{0}^{\infty} \xi L^{-1} \{ \tilde{p}(\xi; \zeta, s) \} J_{0}(\xi r) d\xi , \tag{25}
\]

where the Laplace inversion is defined as

\[
L^{-1} \{ \tilde{p}(\xi; \zeta, s) \} = \frac{1}{2\pi i} \int_{c-i\infty}^{c+i\infty} \tilde{p}(\xi; \zeta, s) \exp(st) ds . \tag{26}
\]

The transient excess pore water pressure \( p(r, z, t) \) of the saturated pervious half space due to a point sink is obtained as following:

\[
p(r, z, t) = \frac{Qr}{4\pi k} \left\{ \frac{1}{\sqrt{r^2 + (z + h)^2}} \text{erfc} \left( \frac{r}{\sqrt{2ct}} \right) - \frac{1}{\sqrt{r^2 + (z - h)^2}} \text{erfc} \left( \frac{r}{\sqrt{2ct}} \right) \right\} . \tag{27}
\]

The long-term excess pore water pressure is derived when \( t \to \infty \). It leads to

\[
p(r, z, \infty) = \frac{Qr}{4\pi k} \left[ \frac{1}{\sqrt{r^2 + (z + h)^2}} - \frac{1}{\sqrt{r^2 + (z - h)^2}} \right] . \tag{28}
\]

5. Numerical Results

5.1 Normalized Numerical Consolidation Results

The particular interest is the settlement of stratum at each stage of the consolidation process. The average consolidation ratio \( U \) is defined as following:

\[
U = \frac{\text{Settlement at time } t}{\text{Settlement at end of compression}} . \tag{29}
\]

The average consolidation ratio \( U \) of the saturated pervious half space can be derived as below:
Figure 4 shows the average consolidation ratio $U$ for $r/h = 0, 1, 2, 5,$ and 10 for the saturated pervious half space. The figure shows that $U$ initially decreases rapidly, and then the rate of settlement reduces. As $U$ approaches 100% asymptotically, the theoretical consolidation is never achieved. The trend revealed in this model agrees with previous models by Sivaram and Swamee (1977) that $U$ initially decreases rapidly, and then the rate of settlement slows down.

The profiles of normalized vertical and horizontal displacements at the ground surface $z = 0$ for different dimensionless time factor $\sqrt{ct/h^2}$ are shown in Figures 5 and 6, respectively. The ground surface reveals significant horizontal displacement. For example, Fig. 6 shows that the maximum surface horizontal displacement is around 30% of the maximum ground settlement at $r/h \approx 1.272$, which can also be found from the ratio of Eqs. (21a) and (21b).

From equations (27) and (28), the profiles of normalized excess pore water pressure $p(r,z,t)/[Qr_0/4\pi kh]$ of the pervious half space at four different dimensionless time factors $\sqrt{ct/h^2} = 1, 2, 3,$ and $\infty$ are illustrated in Fig. 7(a)-(d), respectively. The changes in excess pore water pressure have negative value $p(r,z,t)$ which is caused by suction of groundwater withdrawal. Besides, the larger magnitude of subsidence is due to a wider region influenced by the pumping.

$$U = \frac{2ct}{h^2 + r^2} \text{erf} \left( \frac{\sqrt{h^2 + r^2}}{2\sqrt{ct}} \right) - \frac{2}{\sqrt{h^2 + r^2}} \sqrt{\frac{ct}{\pi}} \exp \left( \frac{-h^2 + r^2}{4ct} \right) + \text{erfc} \left( \frac{\sqrt{h^2 + r^2}}{2\sqrt{ct}} \right).$$  

(30)

Fig. 6. Normalized horizontal displacement profile at the ground surface $z = 0$ for saturated pervious half space.
5.2 Practical Example
The typical values for the elastic coefficients and permeability used in the practical example of the saturated medium dense sand are listed in Table 2.
If the groundwater withdrawal can be regarded as a point sink and the pumping rate of constant strength \( Q = 30 \text{ l/s} = 3 \times 10^{-3} \text{ m}^3/\text{s} \), then it can have a long-term maximum horizontal
displacement and settlement at the ground surface of 1.42 cm and 4.68 cm, respectively. It is noticed from Eqs. (21a) and (21b) that the magnitude of long-term ground surface horizontal displacement and settlement are not directly dependent on the pumping depth \( h \) of the point sink.

6. Conclusions

Closed-form solutions of the transient consolidation due to pumping from pervious saturated elastic half space were obtained by using Laplace and Hankel transformations. The study investigated the vertical and horizontal displacements of the ground surface. It also addressed the excess pore water pressure of the porous elastic half space due to a point sink. The results show:

1. The maximum ground surface horizontal displacement is around 30% of the maximum surface settlement at \( r/h \approx \sqrt{\phi} = 1.272 \), where \( \phi = (1 + \sqrt{5})/2 \approx 1.618 \) is known as the golden ratio. It’s interesting to find that the golden ratio \( \phi \) also appears in the corresponding settlement of the poroelastic half space. The ground surface settlement at \( r = \sqrt{\phi} h \) is around 61.8% of the maximum ground surface settlement.

2. From the average consolidation ratio \( U \) at \( r/h = 0, 1, 2, 5, \) and 10, it shows that \( U \) initially decreases rapidly, and then the rate of settlement reduces.

3. The magnitude of long-term maximum ground surface horizontal displacement and settlement are independent on the pumping depth \( h \) of the point sink.
