1. Introduction

The problem of parameter identification characterizes a typical inverse problem in engineering. It arises from the difficulty in building theoretical models that are able to represent satisfactorily physical phenomena under real operating conditions. Considering the possibility of using more complex models along with the information provided by experimental data, the parameters obtained through an inverse problem approach may then be used to simulate the behavior of the system for different operation conditions. Traditionally, this kind of problem has been treated by using either classical or deterministic optimization techniques (Baltes et al., 1994; Cazzador and Lubenova, 1995; Su and Silva Neto, 2001; Silva Neto and Özisik, 1993ab, 1994; Yan et al., 2008; Yang et al., 2009). In the recent years however, the use of non-deterministic techniques or the coupling of these techniques with classical approaches thus forming a hybrid methodology became very popular due to the simplicity and robustness of evolutionary techniques (Wang et al., 2001; Silva Neto and Soeiro, 2002, 2003; Silva Neto and Silva Neto, 2003; Lobato and Steffen Jr., 2007; Lobato et al., 2008, 2009, 2010).

The solution of inverse problems has several relevant applications in engineering and medicine. A lot of attention has been devoted to the estimation of boundary and initial conditions in heat conduction problems (Alifanov, 1974, Beck et al., 1985, Denisov and Solov’yera, 1993, Muniz et al., 1999) as well as thermal properties (Artyukhin, 1982, Carvalho and Silva Neto, 1999, Soeiro et al., 2000; Su and Silva Neto, 2001; Lobato et al., 2009) and heat source intensities (Borukhov and Kolesnikov, 1988, Silva Neto and Özisik, 1993ab, 1994, Orlande and Özisik, 1993, Moura Neto and Silva Neto, 2000; Wang et al., 2000).
in such diffusive processes. On the other hand, despite its relevance in chemical engineering, there is not a sufficient number of published results on inverse mass transfer or heat convection problems. Denisov (2000) has considered the estimation of an isotherm of absorption and Lugon et al. (2009) have investigated the determination of adsorption isotherms with applications in the food and pharmaceutical industry, and Su et al., (2000) have considered the estimation of the spatial dependence of an externally imposed heat flux from temperature measurements taken in a thermally developing turbulent flow inside a circular pipe. Recently, Lobato et al. (2008) have considered the estimation of the parameters of Page’s equation and heat loss coefficient by using experimental data from a realistic rotary dryer.

Another class of inverse problems in which the concurrence of specialists from different areas has yielded a large number of new methods and techniques for non-destructive testing in industry, and diagnosis and therapy in medicine, is the one involving radiative transfer in participating media. Most of the work in this area is related to radiative properties or source estimation (Ho and Özisik, 1989, McCormick, 1986, 1992, Silva Neto and Özisik, 1995, Kauati et al., 1999). Two strong motivations for the solution of such inverse problems in recent years have been the biomedical and oceanographic applications (McCormick, 1993, Sundman et al., 1998, Kauati et al., 1999, Carita Montero et al., 1999, 2000). The increasing interest on inverse problems (IP) is due to the large number of practical applications in scientific and technological areas such as tomography (Kim and Charette, 2007), environmental sciences (Hanan, 2001) and parameter estimation (Souza et al., 2007; Lobato et al., 2008, 2009, 2010), to mention only a few.

In the radiative problems context, the inverse problem consists in the determination of radiative parameters through the use of experimental data for minimizing the residual between experimental and calculated values. The solution of inverse radiative transfer problems has been obtained by using different methodologies, namely deterministic, stochastic and hybrid methods. As examples of techniques developed for dealing with inverse radiative transfer problems, the following methods can be cited: Levenberg-Marquardt method (Silva Neto and Moura Neto, 2005); Simulated Annealing (Silva Neto and Soeiro, 2002; Souza et al., 2007); Genetic Algorithms (Silva Neto and Soeiro, 2002; Souza et al., 2007); Artificial Neural Networks (Soeiro et al., 2004); Simulated Annealing and Levenberg-Marquard (Silva Neto and Soeiro, 2006); Ant Colony Optimization (Souto et al., 2005); Particle Swarm Optimization (Becceneri et al, 2006); Generalized Extremal Optimization (Souza et al., 2007); Interior Points Method (Silva Neto and Silva Neto, 2003); Particle Collision Algorithm (Knupp et al., 2007); Artificial Neural Networks and Monte Carlo Method (Chalhoub et al., 2007b); Epidemic Genetic Algorithm and the Generalized Extremal Optimization Algorithm (Cuco et al., 2009); Generalized Extremal Optimization and Simulated Annealing Algorithm (Galski et al., 2009); Hybrid Approach with Artificial Neural Networks, Levenberg-Marquardt and Simulated Annealing Methods (Lugon, Silva Neto and Santana, 2009; Lugon and Silva Neto, 2010), Differential Evolution (Lobato et al., 2008; Lobato et al., 2009), Differential Evolution and Simulated Annealing Methods (Lobato et al., 2010).

In this chapter we first describe three problems of heat and mass transfer, followed by the formulation of the inverse problems, the description of the solution of the inverse problems with Simulated Annealing and its hybridization with other methods, and some test case results.
2. Formulation of the Direct Heat and Mass Transfer Problems

2.1 Radiative Transfer

Consider the problem of radiative transfer in an absorbing, emitting, isotropically scattering, plane-parallel, and gray medium of optical thickness $\tau_g$, between two diffusely reflecting boundary surfaces as illustrated in Fig.1. The mathematical formulation of the direct radiation problem is given by (Özişik, 1973)

$$\frac{\partial I(\tau, \mu)}{\partial \tau} + I(\tau, \mu) = \frac{\omega}{2} \int_{-1}^{1} I(\tau, \mu') d\mu', \quad 0 < \tau < \tau_g, \quad -1 \leq \mu \leq 1$$  \hspace{1cm} (1)

$$I(0, \mu) = A_1 + 2\rho_1 \int_{-1}^{1} I(0, -\mu') \mu' d\mu', \quad \mu > 0$$  \hspace{1cm} (2)

$$I(\tau_g, \mu) = A_2 + 2\rho_2 \int_{-1}^{1} I(\tau_g, \mu') \mu' d\mu', \quad \mu < 0$$  \hspace{1cm} (3)

where $I(\tau, \mu)$ is the dimensionless radiation intensity, $\tau$ is the optical variable, $\mu$ is the direction cosine of the radiation beam with the positive $\tau$ axis, $\omega$ is the single scattering albedo, and $\rho_1$ and $\rho_2$ are the diffuse reflectivities. The illumination from the outside is supplied by external isotropic sources with intensities $A_1$ and $A_2$.

No internal source was considered in Eq. (1). In radiative heat transfer applications it means that the emission of radiation by the medium due to its temperature is negligible in comparison to the strength of the external isotropic radiation sources incident at the boundaries $\tau = 0$ and/or $\tau = \tau_g$.

In the direct problem defined by Eqs. (1-3) the radiative properties and the boundary conditions are known. Therefore, the values of the radiation intensity can be calculated for every point in the spatial and angular domains. In the inverse problem considered here the radiative properties of the medium are unknown, but we still need to solve problem (1-3) using estimates for the unknowns.

![Fig. 1. The geometry and coordinates.](www.intechopen.com)
2.2 Drying (Simultaneous Heat and Mass Transfer)

In Fig. 2, adapted from Mwithiga and Olwal (2005), it is represented the drying experiment setup considered in this section. In it was introduced the possibility of using a scale to weight the samples, sensors to measure temperature in the sample, and also inside the drying chamber.

![Drying experiment setup](adapted from Mwithiga and Olwal, 2005).

In accordance with the schematic representation shown in Fig. 3, consider the problem of simultaneous heat and mass transfer in a one-dimensional porous media in which heat is supplied to the left surface of the porous media, at the same time that dry air flows over the right boundary surface.

![Drying process schematic representation](adapted from Mwithiga and Olwal, 2005).

The mathematical formulation used in this work for the direct heat and mass transfer problem considered a constant properties model, and in dimensionless form it is given by (Luikov and Mikhailov, 1965; Mikhailov and Özisik, 1994),
In Fig. 2, adapted from Mwithiga and Olwal (2005), it is represented the drying experiment setup considered in this section. In it was introduced the possibility of using a scale to weight the samples, sensors to measure temperature in the sample, and also inside the drying chamber.

In accordance with the schematic representation shown in Fig. 3, consider the problem of simultaneous heat and mass transfer in a one-dimensional porous media in which heat is supplied to the left surface of the porous media, at the same time that dry air flows over the right boundary surface.

The mathematical formulation used in this work for the direct heat and mass transfer problem considered a constant properties model, and in dimensionless form it is given by (Luikov and Mikhailov, 1965; Mikhailov and Özisik, 1994),

\[
\frac{\partial \theta_1(X, \tau)}{\partial \tau} = a \frac{\partial^2 \theta_1}{\partial X^2} - \beta \frac{\partial \theta_2}{\partial \tau}, \quad 0 < X < 1, \quad \tau > 0
\]  

\[
\frac{\partial \theta_2(X, \tau)}{\partial \tau} = Lu \frac{\partial^2 \theta_1}{\partial X^2} - Lu \frac{\partial \theta_2}{\partial \tau}, \quad 0 < X < 1, \quad \tau > 0
\]  

subject to the following initial conditions, for \( 0 \leq X \leq 1 \)

\[
\theta_1(X, 0) = 0
\]

\[
\theta_2(X, 0) = 0
\]

and to the boundary conditions, for \( \tau > 0 \)

\[
\frac{\partial \theta_1(0, \tau)}{\partial X} = -Q
\]

\[
\frac{\partial \theta_2(0, \tau)}{\partial X} = -Pn Q
\]

\[
\frac{\partial \theta_1(1, \tau)}{\partial X} + Bi_1 \theta_1(1, \tau) = Bi_1 - (1 - \epsilon) Ko Lu Bi_1 \left[ 1 - \theta_1(1, \tau) \right] = 0
\]

\[
\frac{\partial \theta_2(1, \tau)}{\partial X} + Bi_2 \theta_2(1, \tau) = Bi_2 - Pn Bi_1 \left[ \theta_1(1, \tau) - 1 \right]
\]

where

\[
\alpha = 1 + \epsilon Ko Lu Pn
\]

\[
\beta = \epsilon Ko Lu
\]

\[
Bi_1^* = Bi_1 \left[ 1 - (1 - \epsilon) Pn Ko Lu \right]
\]

and the dimensionless variables are defined as

\[
\theta_1(X, \tau) = \frac{T(x, \tau) - T_0}{T_i - T_0}, \text{ temperature}
\]

\[
\theta_2(X, \tau) = \frac{u_i - u(x, \tau)}{u_i - u'}, \text{ moisture potential}
\]

\[
X = \frac{x}{l}, \text{ spatial coordinate}
\]

\[
\tau = \frac{at}{l^2}, \text{ time}
\]

\[
Lu = \frac{a}{\alpha}, \text{ Luikov number}
\]

\[
Pn = \frac{\delta}{u_i - u'}, \text{ Possnov number}
\]

www.intechopen.com
When the geometry, the initial and boundary conditions, and the medium properties are known, the system of equations (4-11) can be solved, yielding the temperature and moisture distribution in the media. The finite difference method was used to solve the system (4-11). Many previous works have studied the drying inverse problem using measurements of temperature and moisture-transfer potential at specific locations of the medium. But to measure the moisture-transfer potential in a certain position is not an easy task, so in this work it is used the average quantity

\[
\bar{u}(t) = \frac{1}{x} \int_{x=0}^{x=1} u(x,t) dx
\]

or

\[
\bar{u}_z(t) = \int_{x=0}^{x=1} \theta_z(x,t) dx
\]

Therefore, in order to obtain the average moisture measurements, \( \bar{u}(t) \), one have just to weight the sample at each time (Lugon and Silva Neto, 2010).

### 2.3 Gas-liquid Adsorption

The mechanism of proteins adsorption at gas-liquid interfaces has been the subject of intensive theoretical and experimental research, because of the potential use of bubble and foam fractionation columns as an economically viable means for surface active compounds recovery from diluted solutions, (Özturk et al., 1987; Deckwer and Schumpe, 1993; Graham and Phillips, 1979; Santana and Carbonell, 1993ab; Santana, 1994; Krishna and van Baten, 2003; Haut and Cartage, 2005; Mouza et al., 2005; Lugon, 2005).

The direct problem related to the gas-liquid interface adsorption of bio-molecules in bubble columns consists essentially in the calculation of the depletion, that is, the reduction of solute concentration with time, when the physico-chemical properties and process parameters are known.

The solute depletion is modeled by

\[
\frac{dC_b}{dt} = \frac{6\nu}{g} \frac{r_{gb}}{(1 - \varepsilon_g)Hd_b \Gamma}
\]
where \( C_b \) is the liquid solute concentration (bulk), \( d_b \) is the bubble diameter, \( H \) is the bubble column height, \( v_g \) is the superficial velocity (gas volumetric flow rate divided by the area of the transversal section of the column \( A \)), and \( \Gamma \) is the surface excess concentration of the adsorbed solute. 

The symbol \( \varepsilon_g \) represents the gas volumetric fraction, which can be calculated from the dimensionless correlation of Kumar (Özturk et al., 1987),

\[
\varepsilon_g = 0.728U - 0.485U^2 + 0.095U^3
\]

where

\[
U = v_s \left[ \frac{\rho_b^2}{\gamma (\rho_b - \rho_g) g} \right]^{1/2}
\]

\( \rho_b \) is the liquid density, \( \gamma \) is the surface tension, \( g \) is the gravity acceleration, and \( \rho_g \) is the gas density.

The quantities \( \Gamma \) and \( C \) are related through adsorption isotherms such as:

(i) Linear isotherm

\[
\Gamma = B + KC
\]

(ii) Langmuir isotherm

\[
\Gamma_i = \frac{1}{d} \left[ \frac{K_i(T)C}{1 + K_i(T)C} \right]
\]

(iii) Two-layers isotherm

\[
\Gamma_i = \Gamma_i + \Gamma_2 = \frac{K_i(T)\exp(-\lambda \Gamma_1)C[1 + K_i(T)\lambda C]}{\lambda [1 + K_i \exp(-\lambda \Gamma_1)C]}
\]

where \( \Gamma_1 \) and \( \Gamma_2 \) are the excess superficial concentration in the first and second adsorption layers respectively (see Fig. 4).

Fig. 4. Schematic representation of the gas-liquid adsorption process in a bubble and foam column.
Considering that the superficial velocity, bubble diameter and column cross section are constant along the column,
\[
\frac{\partial T(z,t)}{\partial z} = \frac{(k_s\alpha) d_b}{6\nu g} \left[ C_s(t) - C_s(z,t) \right]
\]  
(33)
where \( z \) represents the spatial coordinate along the column, \( C_s \) is the solute concentration next to the bubbles and \((k_s\alpha)\) is the volumetric mass transfer coefficient.

There are several correlations available for the determination of \((k_s\alpha)\) but following the recommendation of Deckwer and Schumpe (1993) we have adopted the correlation of Öztürk et al. (1987) in the solution of the direct problem:
\[
Sh = 0.62 \text{Sc}^{0.5} \text{Bo}^{0.13} \text{Ga}^{0.24} \left( \frac{Vr}{\sqrt{gd_b}} \right)^{0.68} \left( \frac{\rho_c}{\rho} \right)^{0.04}
\]  
(34)
where
\[
\text{Sc} = \left( \frac{V_l}{D_i} \right), \text{ Schmidt number}
\]  
(35)
\[
Sh = \frac{(k_s\alpha)d_b^2}{D_i}, \text{ Sherwood number}
\]  
(36)
\[
\text{Bo} = \frac{V_l}{D_i}, \text{ Bond number}
\]  
(37)
\[
\text{Ga} = \frac{gd_b^3}{V_l^2}, \text{ Galilei Number}
\]  
(38)

\( D_i \) is the tensoactive diffusion coefficient and \( V_l \) is the liquid dynamic viscosity.

Combining Eqs. (27) and (33) and using an initial condition, such as \( C_s = C_{so} \) when \( t = 0 \), and a boundary condition, like \( \Gamma = 0 \) at \( z = 0 \), the solute concentration can be calculated as a function of time, \( C_s(t) \). Santana and Carbonell (1993ab) developed an analytical solution for the direct problem in the case of a linear adsorption isotherm and the results presented a good agreement with experimental data for BSA (Bovine Serum Albumin).

In order to solve Eq. (27) a second order Runge Kutta method was used, known as the mid point method. Given the physico-chemical and process parameters, as well as the boundary and initial conditions, the solute concentration can be calculated for any time \( t \) (Lugon et al., 2009).

### 3. Formulation of Inverse Heat and Mass Transfer Problems

The inverse problem is implicitly formulated as a finite dimensional optimization problem (Silva Neto and Soeiro, 2003; Silva Neto and Moura Neto, 2005), where one seeks to minimize the cost functional of squared residues between the calculated and experimental values for the observable variable,

\[
S(P) = [G_{calc}(P) - G_{mean}(P)]^T W [G_{calc}(P) - G_{mean}(P)] = F^T F
\]  
(39a)
where $\mathbf{G}_{\text{meas}}$ is the vector of measurements, $\mathbf{G}_{\text{calc}}$ is the vector of calculated values, $\mathbf{P}$ is the vector of unknowns, $\mathbf{W}$ is the diagonal matrix whose elements are the inverse of the measurement variances, and the vector of residues $\mathbf{F}$ is given by

$$\mathbf{F} = \mathbf{G}_{\text{calc}}(\mathbf{P}) - \mathbf{G}_{\text{calc}}(\mathbf{P})$$

(39b)

The inverse problem solution is the vector $\mathbf{P}^*$ which minimizes the norm given by Eq. (39a), that is:

$$S(\mathbf{P}^*) = \min_{\mathbf{P}} S(\mathbf{P})$$

(40)

Depending on the direct problem, different measurements are to be taken, that is:

a) Radiative problem
Using calculated values given by Eq. (1) and experimental radiation intensities at the boundaries $\tau = 0$ and $\tau = \tau_0$, as well as at points that belong to the set $\Omega$ (points inside the domain $\tau$ - internal detectors) we try to estimated the vector of unknowns $\mathbf{P}$ considered. Two different vectors of unknowns $\mathbf{P}$ are possibly considered for the minimization of the difference between the experimental and calculated values: (i) $\tau_0, \omega, \rho_1$ and $\rho_2$; (ii) $\tau_0, \omega, A_1$ and $A_2$.

b) Drying problem
Using temperature measurements, $T$, taken by sensors located inside the medium, and the average of the moisture-transfer potential, $\overline{\mathbf{P}}$, during the experiment, we try to estimate the vector of unknowns $\mathbf{P}$, for which a combination of variables was used: $L_u$ (Luikov number), $\delta$ (thermogradient coefficient), $r/c$ (relation between latent heat of evaporation and specific heat of the medium), $h/k$ (relation between heat transfer coefficient and thermal conductivity), and $h_{\text{out}}/k_{\text{in}}$ (relation between mass transfer coefficient and mass conductivity).

c) Gas-liquid adsorption problem
Different vectors of unknowns $\mathbf{P}$ are possibly considered, which are associated with different adsorption isotherms: (i) $K$ and $B$ (Linear isotherm); (ii) $K_s(T)$ and $\hat{a}$ (Langmuir isotherm); (iii) $K_s(T), K_s(T), \lambda$ and $\hat{a}$ (two-layers isotherm). Here the BSA (Bovine Serum Albumin) adsorption was modeled using a two-layer isotherm.  

4. Solution of the Inverse Problems with Simulated Annealing and Hybrid Methods

4.1 Design of Experiments
The sensitivity analysis plays a major role in several aspects related to the formulation and solution of an inverse problem (Dowding et al., 1999; Beck, 1988). Such analysis may be performed with the study of the sensitivity coefficients. Here we use the modified, or scaled, sensitivity coefficients.
\[ SC_{P_j(t)} = P_j \frac{\partial V(t)}{\partial P_j}, \quad j = 1, 2, ..., N_p \]  

where \( V \) is the observable state variable (which can be measured), \( P_j \) is a particular unknown of the problem, and \( N_p \) is the total number of unknowns considered.

As a general guideline, the sensitivity of the state variable to the parameter we want to determine must be high enough to allow an estimate within reasonable confidence bounds. Moreover, when two or more parameters are simultaneously estimated, their effects on the state variable must be independent (uncorrelated). Therefore, when represented graphically, the sensitivity coefficients should not have the same shape. If they do it means that two or more different parameters affect the observable variable in the same way, being difficult to distinguish their influences separately, which yields to poor estimations.

Another important tool used in the design of experiments is the study of the matrix

\[
\mathbf{SC} = \begin{bmatrix}
SC_{P_1 V_1} & SC_{P_1 V_2} & \ldots & SC_{P_1 V_m} \\
SC_{P_2 V_1} & SC_{P_2 V_2} & \ldots & SC_{P_2 V_m} \\
\vdots & \vdots & \ddots & \vdots \\
SC_{P_m V_1} & SC_{P_m V_2} & \ldots & SC_{P_m V_m}
\end{bmatrix}
\]  

where \( V_i \) is a particular measurement of temperature or moisture potential and \( m \) is the total number of measurements.

Maximizing the determinant of the matrix \( \mathbf{SC}^T \mathbf{SC} \) results in higher sensitivity and uncorrelation (Beck, 1988).

### 4.2 Simulated Annealing Method (SA)

Based on statistical mechanics reasoning, applied to a solidification problem, Metropolis et al. (1953) introduced a simple algorithm that can be used to accomplish an efficient simulation of a system of atoms in equilibrium at a given temperature. In each step of the algorithm a small random displacement of an atom is performed and the variation of the energy \( \Delta E \) is calculated. If \( \Delta E < 0 \) the displacement is accepted, and the configuration with the displaced atom is used as the starting point for the next step. In the case of \( \Delta E > 0 \), the new configuration can be accepted according to Boltzmann probability

\[ P(\Delta E) = \exp(-\Delta E / k_BT) \]  

A uniformly distributed random number \( p \) in the interval \([0,1]\) is calculated and compared with \( P(\Delta E) \). Metropolis criterion establishes that the new configuration is accepted if \( p < P(\Delta E) \), otherwise it is rejected and the previous configuration is used again as a starting point.

Using the objective function \( S(P) \), given by Eq. (39a), in place of energy and defining configurations by a set of variables \( \{P_i\}, i = 1, 2, ..., N_p \), where \( N_p \) represents the number of unknowns we want to estimate, the Metropolis procedure generates a collection of
configurations of a given optimization problem at some temperature \( T \) (Kirkpatrick et al., 1983). This temperature is simply a control parameter. The simulated annealing process consists of first “melting” the system being optimized at a high “temperature”, then lowering the “temperature” until the system “freezes” and no further change occurs.

The main control parameters of the algorithm implemented (“cooling procedure”) are the initial “temperature”, \( T_0 \), the cooling rate, \( r, \) number of steps performed through all elements of vector \( \mathbf{P}, N_s, \) number of times the procedure is repeated before the “temperature” is reduced, \( N_r, \) and the number of points of minimum (one for each temperature) that are compared and used as stopping criterion if they all agree within a tolerance \( \varepsilon, N_e. \)

### 4.3 Levenberg-Marquardt Method (LM)

The Levenberg-Marquardt is a deterministic local optimizer method based on the gradient (Marquardt, 1963). In order to minimize the functional \( S(\mathbf{P}) \) we first write

\[
\frac{dS}{d\mathbf{P}} = \frac{d}{d\mathbf{P}} (\mathbf{F}^T \mathbf{F}) = 0 \rightarrow \mathbf{J}^T \mathbf{J} = 0
\]

where \( \mathbf{J} \) is the Jacobian matrix, with the elements \( J_{ps} = \frac{\partial C_{ts}}{\partial P_s} \) being \( p = 1, 2, ..., M, \) and \( s = 1, 2, ..., N_s, \) where \( M \) is the total number of measurements and \( N_s \) is the number of unknowns. It is observed that the elements of the Jacobian matrix are related to the scaled sensitivity coefficients presented before.

Using a Taylor’s expansion and keeping only the terms up to the first order,

\[
\mathbf{F}(\mathbf{P} + \Delta \mathbf{P}) \equiv \mathbf{F}(\mathbf{P}) + \mathbf{J}\Delta \mathbf{P}
\]

Introducing the above expansion in Eq. (44) results

\[
\mathbf{J}^T \Delta \mathbf{P} = -\mathbf{J}^T \mathbf{F}(\hat{\mathbf{P}})
\]

In the Levenberg-Marquardt method a damping factor \( \rho^n \) is added to the diagonal of matrix \( \mathbf{J}^T \mathbf{J} \) in order to help to achieve convergence.

Equation (46) is written in a more convenient form to be used in the iterative procedure,

\[
\Delta \mathbf{P}^n = -\left[(\mathbf{J}^n)^T \mathbf{J}^n + \rho^n \mathbf{I}\right]^{-1} (\mathbf{J}^n)^T \mathbf{F}(\mathbf{P}^n)
\]

where \( \mathbf{I} \) is the identity matrix and \( n \) is the iteration index.

The iterative procedure starts with an estimate for the unknown parameters, \( \mathbf{P}^0, \) being new estimates obtained with \( \mathbf{P}^{n+1} = \mathbf{P}^n + \Delta \mathbf{P}^n, \) while the corrections \( \Delta \mathbf{P}^n \) are calculated with Eq. (46). This iterative procedure is continued until a convergence criterion such as

\[
\left| \Delta P^n_s / P^n_s \right| < \varepsilon, \quad n = 1, 2, ..., N_p
\]
is satisfied, where \( \varepsilon \) is a small number, e.g. 10\(^{-5}\).

The elements of the Jacobian matrix, as well as the right side term of Eq. (47), are calculated at each iteration, using the solution of the problem with the estimates for the unknowns obtained in the previous iteration.

### 4.4 Artificial Neural Network (ANN)

The multi-layer perceptron (MLP) is a collection of connected processing elements called nodes or neurons, arranged in layers (Haykin, 1999). Signals pass into the input layer nodes, progress forward through the network hidden layers and finally emerge from the output layer (see Fig. 5). Each node \( i \) is connected to each node \( j \) in its preceding layer through a connection of weight, \( w_{ij} \), and similarly to nodes in the following layer.

![Multi-layer perceptron network](image)

Fig. 5. Multi-layer perceptron network.

A weighted sum is performed at \( i \) of all the signals \( x_j \) from the preceding layer, yielding the excitation of the node; this is then passed through a nonlinear activation function, \( f \), to emerge as the output of the node \( x_i \) to the next layer, as shown by the equation

\[
y_i = f \left( \sum_j w_{ij} x_j \right)
\]

(49)

Various choices for the function \( f \) are possible. Here the hyperbolic tangent function \( f(x) = \tanh(x) \) is used.

The first stage of using an ANN to model an input-output system is to establish the appropriate values for the connection weights \( w_{ij} \). This is the “training” or learning phase. Training is accomplished using a set of network inputs for which the desired outputs are known. These are the so-called patterns, which are used in the training stage of the ANN. At each training step, a set of inputs are passed forward through the network yielding trial outputs which are then compared to the desired outputs. If the comparison error is considered small enough, the weights are not adjusted. Otherwise the error is passed backwards through the net and a training algorithm uses the error to adjust the connection weights. This is the back-propagation algorithm.
Once the comparison error is reduced to an acceptable level over the whole training set, the training phase ends and the network is established. The parameters of a model (output) may be determined using the real experimental data, which are inputs of the established neural network. This is the generalization stage in the use of the ANN. More details can be found in (Soeiro et al., 2004).

4.5 Differential Evolution
The Differential Evolution (DE) is a structural algorithm proposed by Storn and Price (1995) for optimization problems. This approach is an improved version of the Goldberg’s Genetic Algorithm (GA) (Goldberg, 1989) for faster optimization and presented the following advantages: simple structure, easiness of use, speed and robustness (Storn and Price, 1995). Basically, DE generates trial parameter vectors by adding the weighted difference between two population vectors to a third vector. The key parameters of control in DE are the following: \( N \), the population size, \( CR \), the crossover constant and, \( D \), the weight applied to random differential (scaling factor). Storn and Price (1995) have given some simple rules for choosing key parameters of DE for any given application. Normally, \( N \) should be about 5 to 10 times the dimension (number of parameters in a vector) of the problem. As for \( D \), it lies in the range 0.4 to 1.0. Initially, \( D = 0.5 \) can be tried, and then \( D \) and/or \( N \) is increased if the population converges prematurely.

DE has been successfully applied to various fields such as digital filter design (Storn, 1995), batch fermentation process (Chiou and Wang, 1999), estimation of heat transfer parameters in a bed reactor (Babu and Sastry, 1999), synthesis and optimization of heat integrated distillation system (Babu and Singh, 2000), optimization of an alklylation reaction (Babu and Gaurav, 2000), parameter estimation in fed-batch fermentation process (Wang et al., 2001), optimization of thermal cracker operation (Babu and Angira, 2001), engineering system design (Lobato and Steffen, 2007), economic dispatch optimization (Coelho and Mariani, 2007), identification of experimental data (Maciejewski et al., 2007), apparent thermal diffusivity estimation during the drying of fruits (Mariani et al., 2008), estimation of the parameters of Page’s equation and heat loss coefficient by using experimental data from a realistic rotary dryer (Lobato et al., 2008), solution of inverse radiative transfer problems (Lobato et al., 2009, 2010), and other applications (Storn et al., 2005).

4.6 Combination of ANN, LM and SA Optimizers
Due to the complexity of the design space, if convergence is achieved with a gradient based method it may in fact lead to a local minimum. Therefore, global optimization methods are required in order to reach better approximations for the global minimum. The main disadvantage of these methods is that the number of function evaluations is high, becoming sometimes prohibitive from the computational point of view (Soeiro et al., 2004).

In this chapter, different combinations of methods are used for the solution of inverse heat and mass transfer problems, involving in all cases Simulated Annealing as the global optimizer:

a) when solving radiative inverse problems, it was used a combination of the LM and SA;
b) when solving adsorption and drying inverse problems, it was used a combination of ANN, LM and SA.

Therefore, in all cases it was run the LM, reaching within a few iterations a point of minimum. After that we run the SA. If the same solution is reached, it is likely that a global
minimum was reached, and the iterative procedure is interrupted. If a different solution is obtained it means that the previous one was a local minimum, otherwise we could run again the LM and SA until the global minimum is reached.

When using the ANN method, after the training stage one is able to quickly obtain an inverse problem solution. This solution may be used as an initial guess for the LM. Trying to keep the best features of each method, we have combined the ANN, LM and SA methods.

5. Test Case Results

5.1 Radiative Transfer

5.1.1 Estimation of \( \{r_0, \omega, \rho_1, \rho_2\} \) using LM-SA combination

The combined LM-SA approach was applied to several test problems. Since there were no real experimental data available, they were simulated by solving the direct problem and considering the output as experimental data. These results may be corrupted by random multipliers representing a white noise in the measuring equipment. In this effort, since we are developing the approach and trying to compare the performance of the optimization techniques involved, the output was considered as experimental result without any change.

The direct problem is solved with a known vector \( \{r_0, \omega, \rho_1, \rho_2\} \), which will be considered as the exact solution for the inverse problem. The correspondent output is recorded as experimental data. Now we begin the inverse problem with an initial estimate for the above quantities, obviously away from the exact solution. The described approach is, then, used to find the exact solution.

In a first example the exact solution vector was assumed as \( \{1.0, 0.5, 0.1, 0.95\} \) and the initial estimate as \( \{0.1, 0.1, 0.1, 0.1\} \). Using both methods the exact solution was obtained. The difference was the computational effort required as shown in Table 1.

The difficulty encountered by LM in converging to the right solution was due to a large plateau that exists in the design space for values of \( \tau_o \) between 6.0 and 10.0. In this interval the objective function has a very small variation. The SA solved the problem with the same performance as in the first example. The combination of both methods was then applied. SA was let running for only one cycle (400 function evaluations). At this point, the current optimum was \([0.94, 0.43, 0.61, 0.87]\), far from the plateau mentioned above. With this initial estimate, LM converged to the right solution very quickly in four iterations, as shown in Table 3.

### 5.1.2 Estimation of \( \{ \omega, \tau_o, A_1, A_2 \} \) using SA and DE

In order to evaluate the performance of the methods of Simulated Annealing and Differential Evolution for the simultaneous estimation of both the single scattering albedo, \( \omega \), and the optical thickness, \( \tau_o \), of the medium, and also the intensities \( A_1 \) and \( A_2 \) of the external sources at \( \tau = 0 \) and \( \tau = \tau_o \), respectively, of a given one-dimensional plane-parallel participating medium, the four test cases listed in Table 4 have been performed (Lobato et al., 2010).

Table 8. Results obtained for case 3.
The present case studies used synthetic experimental data considering 20 control elements for \( \mu \) and 20 control elements for \( \tau \), resulting in 400 synthetic experimental points, that is, 40 (2 x 20) representing points along the boundaries and 360 (18 x 20) inside the domain.

In Table 6 the results obtained for case 1 are presented. It can be observed that when using noiseless data both algorithms presented good estimates for the unknown parameters. However, if noise is increased, it can be observed that the optimal values of the parameters demonstrate that the estimates are poorer. The same behavior was observed for test cases 2-4 whose results are presented in Tables 7-9, respectively. However, the results obtained can be considered satisfactory.

The comparisons between the two algorithms are done according to the perspective of both the number of function evaluations (NF) and the running time (cputime) given in minutes. The present case studies used synthetic experimental data considering 20 control elements to discretize \( \mu \) and 20 control elements for \( \tau \), resulting in 400 synthetic experimental points, that is, 40 (2 x 20) representing points along the boundaries and 360 (18 x 20) inside the domain.

In Table 6 the results obtained for case 1 are presented. It can be observed that when using noiseless data both algorithms presented good estimates for the unknown parameters. However, if noise is increased, it can be observed that the optimal values of the parameters demonstrate that the estimates are poorer. The same behavior was observed for test cases 2-4 whose results are presented in Tables 7-9, respectively. However, the results obtained can be considered satisfactory.

Table 9. Results obtained for case 4.

* NF=1010, cputime= 16.3987 min and ** NF=8888, cputime= 58.9858 min.
The present case studies used synthetic experimental data considering 20 control elements, the number of function evaluations (\(NF\)). The comparisons between the two algorithms are done according to the perspective of both the medium and the air, location of temperature sensors, experiment duration, etc. In this work instead, \(\delta\), \(r/c\), \(h/k\) and \(h_o/k_o\) are estimated using an “optimum” experiment (Dowding et al., 1999 and Beck, 1988) for wood drying, and doing so, it was considered also the following process control parameters: heat flux, \(Q\), the medium width, \(l\), the difference between the medium and the air, \(dT = T_m - T_o\), and the difference between the moisture potential between the medium and the air, \(du = u_m - u_o\).

There is no difference between the sensitivity coefficients for the two sets of variable, that is, the scaled sensitivity coefficients are exactly the same for both vectors \([L_u, P_n, K_o, B_i, B_m, \varepsilon]^T\) and \([L_u, \delta, r/c, h/k, h_o/k_o, \varepsilon]^T\).

\[
SC_{\delta}(X, \tau) = \delta \frac{\partial V(X, \tau)}{\partial \delta} = P_n \frac{\partial V(X, \tau)}{\partial P_n} = SC_{P_n}(X, \tau) \tag{50}
\]

\[
SC_{r/c}(X, \tau) = r/c \frac{\partial V(X, \tau)}{\partial r/c} = K_o \frac{\partial V(X, \tau)}{\partial K_o} = SC_{K_o}(X, \tau) \tag{51}
\]

\[
SC_{h/k}(X, \tau) = h/k \frac{\partial V(X, \tau)}{\partial h/k} = B_i \frac{\partial V(X, \tau)}{\partial B_i} = SC_{B_i}(X, \tau) \tag{52}
\]

\[
SC_{h_m/k_m}(X, \tau) = h_m/k_m \frac{\partial V(X, \tau)}{\partial h_m/k_m} = B_m \frac{\partial V(X, \tau)}{\partial B_m} = SC_{B_m}(X, \tau) \tag{53}
\]

The reasons for changing the estimated variables are the use of the design of experiment tools and interpretation. Consider the heat and mass Biot numbers for example. If one changes the media width, \(l\), both heat and mass Biot numbers changes. The mathematical...
problem would be different, even though the material is still the same, because one is estimating two different heat and mass Biot numbers. In order to solve this problem, it was decided to estimate the relation between heat transfer coefficient and thermal conductivity, \( h/k \), and the relation between mass transfer coefficient and mass conductivity, \( h_m/k_m \), so that we could change the media width and continue with the same value for both variables to be estimated.

The same idea was used, choosing to estimate the thermogradients coefficient (\( \delta \)) and the relation between latent heat of evaporation and specific heat of the medium (\( c_r/c \)), instead of the Possnov (\( Pn \)) and Kossovitch (\( Ko \)) numbers. Doing so, one is able to optimize the experiment considering the difference between the medium and the air temperatures, \( dT = T_o - T_s \), and the difference between the moisture-transfer potential between the media and the air, \( du = u_o - u^* \), without affecting the estimated parameters values.

In Fig. 7 it is represented the variation of the value of the matrix \( SC^TSC \) determinant as a function of the temperature differences and moisture potential differences between the medium and the air flowing over it. It is not difficult to understand that one could not build such a graph using a vector of unknown parameters containing Possnov (\( Pn \)) and Kossovitch (\( Ko \)) numbers. In order to achieve greater sensitivities, while the temperature difference has to be the lowest, the moisture potential difference has to be the highest possible. The solid square represents the chosen designed experiment, considering the existence of practical difficulties that may limit our freedom of choice.

![Fig. 7. Determinant of matrix \( Y^TY \) as a function of temperature (\( dT \)) and moisture potential (\( du \)) differences.](www.intechopen.com)

In Fig. 8 it is represented the values of the determinant of matrix \( SC^TSC \) for different values of the heat flux \( Q \) and media thickness \( l \). It is also easy to understand that one could not build such a graph using a vector of unknown parameters containing heat and mass Biot numbers. For practical reasons it was chosen to limit the sample temperature to 130° C. In Fig. 8 the same curve has a continuous-line part and a dashed-line one, when the sample temperature exceeds the limit of 130° C. The solid square shows the chosen designed experiment.

![www.intechopen.com](www.intechopen.com)
Fig. 8. Determinant of \( \text{SC}^T \text{SC} \) matrix for different values of the heat flux \( Q \) and medium thickness \( l \).

Considering the previous analysis of the sensitivity graphs and matrix \( \text{SC}^T \text{SC} \) determinant, it was designed the experiment whose geometric and process parameters are shown in Table 10. Since the average moisture potential, \( \theta \), is more difficult to measure than temperature, \( \theta \), the measurement interval for the average moisture potential, \( \Delta \tau_{\theta} \), was considered larger than the interval for the temperature \( \Delta \tau_{T} \).

Table 10. Reference values for the designed experiment.

An experiment was designed to perform the simultaneous estimation of \( L_u, \delta, r/c, h/k \) and \( h_u/k_u \). In order to study the proposed method, since real experiment data were not available, we generated synthetic data using

\[
\begin{align*}
\theta_{\text{meas},i} &= \theta_{\text{calc},i} (P_{\text{exact}}) + \sigma_{\theta_i} r_i, \ i = 1, 2, ..., M_{\theta} \\
\tilde{u}_{\text{meas},i} &= \tilde{u}_{\text{meas},i} (P_{\text{exact}}) + \sigma_{\tilde{u}_i} r_i, \ i = 1, 2, ..., M_{\tilde{u}}
\end{align*}
\]

(54a) (54b)

where \( r_i \) are random numbers in the range \([-1,1]\), \( M_{\theta} \) and \( M_{\tilde{u}} \) represent the total number of temperature and moisture-transfer potential experimental data, and \( \sigma_{\theta_i} \) and \( \sigma_{\tilde{u}_i} \) emulates the standard deviation of measurement errors. It was established a standard deviation of
\( \sigma_\theta = 0.03 \) considering 100 temperature measurements \((\Delta \tau = 0.2)\), resulting in a maximum error of 2\%, and \( \sigma_\varphi = 0.001 \) considering 20 moisture measurements \((\Delta \tau = 1.0)\), resulting in a maximum error of 4\%.

In Fig. 9 the graphics of temperature \( (\theta) \) and moisture potential \( (\varphi) \) measurements are presented. The continuous line represents the direct problem solution and the squares represent noisy data. In order to show a better representation, only 20 temperature \( (\theta) \) measurements were represented.

The results obtained using the methods LM 1 (gradient approximated by FDM – Finite Difference Method), LM 2 (gradient approximated by ANN – Artificial Neural Network), ANN, SA and hybrid combinations, for different levels of noise represented by different values of the standard deviation of measurements errors in temperature and average moisture potential, \( \sigma_\theta \) and \( \sigma_\varphi \), respectively in Eqs. (54a,b) are shown in Table 11.

The results obtained using the methods LM 1 (gradient approximated by FDM – Finite Difference Method), LM 2 (gradient approximated by ANN – Artificial Neural Network), ANN, SA and hybrid combinations, for different levels of noise represented by different error of 2%, and maximum error of 4%.

One observes that when there is no noise, that is, the standard deviation of measurements errors are zero, the LM method was able to estimate all variables very quickly (see test cases 1 and 2). When noise is introduced, the LM is retained by local minima (test cases 3 and 4); the ANN did not reach a good solution, but quickly got close to it (test case 5). The ANN solution was then used as a first guess for the LM method with good performance in test cases 6 and 7. The SA reached a good solution but required the largest CPU time, and finally the combination of all methods was able to reach a good solution, without being retained by local minima without taking too much time, i.e. one sixth of the SA time. The time shown in the eleventh column of Table 11 corresponds to the CPU time on a Pentium IV 2.8 GHz processor.

### 5.3 Gas-liquid Adsorption

Recently, the inverse problem of interface adsorption has attracted the attention of an increasing number of researchers (Lugon, 2005; Forssén et al., 2006; Garnier et al., 2007; Voelkel and Strzemiecka, 2007; Ahmad and Guiochon, 2007).

In order to solve the inverse problem of gas-liquid adsorption considering the two-layer isotherm given by Eq. (32), it was necessary to design two different experiments. One to estimate \( K(T) \) and \( \hat{a} \), called experiment 1, and another one to estimate \( \hat{\lambda} \), called experiment 2. In all cases studied the sensitivity to \( K(T) \) is low and therefore this parameter was not estimated with the inverse problem solution.

In Fig. 10 are shown the sensitivity coefficients related to the parameters \( K(T) \), \( K(T) \), \( \lambda \) and \( \hat{a} \) in experiment 1. It is observed that the sensitivity to \( K(T) \) and \( \hat{a} \) for BSA (Bovine Serum Albumin) are higher than the sensitivity to the other parameters and their shapes are different.

Fig. 10. Scaled sensitivity coefficients for BSA – Experiment 1.

In Fig. 11 are shown the sensitivity coefficients related to the parameters \( K(T) \), \( K(T) \), \( \lambda \) and \( \hat{a} \) for BSA in experiment 2. It is observed that the sensitivity to \( \lambda \) is higher than the sensitivity to the other parameters.

Another important tool used in the design of experiments is the study of the matrix \( STSC \), that is, maximizing the determinant of the matrix \( STSC \) results in higher sensitivity and uncorrelation (Dowding et al., 1999).

The difference between the two experiments is related to the BSA concentration, being larger in the first experiment (see Table 12).

In Fig. 12 are shown the values of the determinant of the matrix \( STSC \) for BSA in experiment 1. The designed experiment is marked with a full square. Its choice is justified by the small gain in sensitivity considering the operational difficulties in using a longer column or a higher superficial velocity.

Considering the analysis of the sensitivity graphs and the determinant of the matrix \( STSC \), two experiments were designed, one to estimate \( K(T) \) and \( \hat{a} \), and another to estimate \( \lambda \), as shown in Table 12.

The results achieved using the ANN, LM 1 (gradient approximated by FDM), LM 2 (gradient approximated by ANN), SA and hybrid combinations, for different standard deviations for the measurements errors, \( \sigma \), are shown in Tables 13 and 14.
In Fig. 10 are shown the sensitivity coefficients related to the parameters \( K(T) \), \( \lambda \) and \( \hat{a} \) in experiment 1. It is observed that the sensitivity to \( \lambda \) and \( \hat{a} \) for BSA (Bovine Serum Albumin) are higher than the sensitivity to the other parameters and their shapes are different.

The exact value used is: \( \lambda = 1.117 \text{ m}^2 / \text{ mg} \).
Table 14. Results obtained using ANN, LM 1, LM 2, SA and hybrid combinations for experiment 2.

Test cases 3-9 used simulated artificial data generated with the direct problem solution corrupted with white gaussian noise with standard deviation $\sigma = 0.10\text{mg/l}$, which corresponds to measurement errors of the order of 3%. While in test cases numbers 1, 2, 3, 4 and 8 the initial guess is $\lambda = 0.700\text{m}^2/\text{mg}$, in test cases numbers 6, 7 and 9 the initial guesses are the estimates obtained with the ANN.

6. Conclusions

6.1 Radiative Transfer

6.1.1 Estimation of $\{r_{0}, \omega, \rho_{1}, \rho_{2}\}$ using LM-SA combination

A combination of SA (global optimization method) and LM (local optimization method) was used to solve the inverse radiative transfer problem. It was demonstrated its effectiveness in the solution of this type of problems since one can guarantee the convergence to a good approximation of the global optimum with higher accuracy and less computational effort if it is compared with the application of any global optimization method alone.

6.1.2 Estimation of $\{\omega, r_{0}, A_{1}, A_{2}\}$ using SA and DE

In the present work, the effectiveness of using Differential Evolution and Simulated Annealing for the estimation of radiative properties through an inverse problem approach was analyzed. In this sense, four benchmark cases were studied and it was possible to conclude that both algorithms led to good results for an acceptable number of generations. It should be pointed out that the Differential Evolution Algorithm led to optimal values that are very similar to those obtained by Simulated Annealing, requiring however a smaller number of objective function evaluations. This result was expected, since for the Simulated Annealing Algorithm, for a given iteration, every “temperature” is submitted to a proper number of internal iterations for refinement purposes making the evolutionary process longer, thus increasing the total processing time. On the other hand, as previously mentioned in the works of Storn and Price (1995), Storn (1999) and Angira and Babu (2005), the number of evaluations of the objective function resulting from the Differential Evolution Algorithm is smaller because the evolution scheme is much simpler.

Another interesting aspect is that by adding noise to the synthetic experimental points result an increase in the objective function values, as observed in Tables 6 to 9. Such a behavior was previously expected since noise does not permit the convergence of the optimization algorithm to the exact values of the parameters. Consequently, the user should be aware of this behavior when using real experimental data, which is always affected by noise.

6.2 Drying (Simultaneous Heat and Mass Transfer)

The direct problem of simultaneous heat and mass transfer in porous media modeled with Luikov equations can be solved using the finite difference method, yielding the temperature and moisture distribution in the media, when the geometry, the initial and boundary conditions, and the medium properties are known.
Inverse problem techniques can be useful to estimate the medium properties when they are not known. After the use of an experiment design technique, the hybrid combination ANN-LM-SA resulted in good estimates for the drying inverse problem using artificially generated data.

The design of experiments technique is of great importance for the success of the estimation efforts, while previous works studied the estimation of \( \frac{\partial u}{\partial t} \) and \( \frac{\partial^2 u}{\partial x^2} \), in this work it was considered \( L_{a}, \delta, \frac{r/c}{\mu}, h/f \) and \( h_{m}/k_{a} \). The main advantage of such approach is to be able to design an “optimum” experiment using different medium width, \( l \), porous medium and air temperature difference, \( T_{s}-T_{r} \), and porous medium and air moisture potential difference, \( u_{m}-u' \).

The combination of deterministic (LM) and stochastic (ANN and SA) methods achieved good results, reducing the time needed and not being retained by local minima. The use of ANN to obtain the derivatives in the first steps of the LM method reduced the time required for the solution of the inverse problem.

6.3 Gas-liquid Adsorption

After the use of an experiment design technique, the hybrid combination ANN-LM-SA resulted in good solutions for the gas-liquid adsorption isotherm inverse problem.

The use of the ANN to obtain the derivatives in the first step of the LM method reduced the time necessary to solve the inverse problem.

The book contains 15 chapters presenting recent contributions of top researchers working with Simulated Annealing (SA). Although it represents a small sample of the research activity on SA, the book will certainly serve as a valuable tool for researchers interested in getting involved in this multidisciplinary field. In fact, one of the salient features is that the book is highly multidisciplinary in terms of application areas since it assembles experts from the fields of Biology, Telecommunications, Geology, Electronics and Medicine.
