B-site Multi-element Doping Effect on Electrical Property of Bismuth Titanate Ceramics

Jungang Hou¹ and R. V. Kumar²

¹School of Metallurgical and Ecological Engineering, University of Science and Technology China
²Department of Materials Science and Metallurgy, University of Cambridge United Kingdom

1. Introduction

This article represents a systematic review of the behaviour of B-site multi-element doping effect on electrical property of bismuth titanate ceramics. Bismuth titanate, Bi₄Ti₃O₁₂ (BIT) is a potential candidate for high-temperature device applications due to their high dielectric constant, Curie temperature (Tc), breakdown strength, anisotropy and, low dielectric dissipation factor, therefore attracting considerable commercial interest in applications such as high temperature piezoelectric devices, memory storage and optical displays. These features make bismuth layer-structured ferroelectrics (BLSFs) attractive in the field of developing lead-free piezoelectric materials. BIT is a well-known member of the BLSFs, which can be represented by a general formula (Bi₂O₂)²⁺(Am⁻¹BmO₃m+1)²⁻, where A represents a mono-, di, or trivalent ion, such as La³⁺, Nd³⁺, Pr³⁺, Sm³⁺, etc., B stands for transition-metal cations like Ti⁴⁺, Nb⁵⁺, Ta⁵⁺, W⁶⁺, etc., and m is the number of BO₆ octahedra in the perovskite-like layer (m=1-5) (Aurivillius, 1949; Kumar, 2001; Markovec, 2001; Nagata, 1999; Noguchi, 2000; Sugibuchi, 1975; Shimakawa, 2000; Subbarao, 1961; Shulman, 2000; Shimazu, 1980; Takenaka, 1981). The layer structure of Bi₄Ti₃O₁₂ (m=3) consists of three perovskite-like (Bi₂Ti₂O₁₀)²⁻ units with a pseudo-perovskite layer structure, sandwiched between (Bi₂O₂)²⁺ layers along its crystallographic c axis. In the (Bi₂Ti₂O₁₀)²⁻ units, Ti ions are encased by oxygen octahedra, and Bi ions occupy the spaces in the framework of octahedral (Subbarao, 1950).

BIT is of interest in high-temperature piezoelectric sensors, because it remains ferroelectric up to 675 °C and offers relatively high piezoelectric property (Subbarao, 1961). However, the high leakage current and domain pinning due to defects in BIT have appeared as obstacles for further applications. The reasons for such problems are suggested due to the instability in the oxidation state of Ti ions and the volatile property of Bi during the sintering process (Nagata, 1999). Great efforts have been made to solve the high-leakage current, by incorporation of W, Nb or Ta dopants, as these can significantly decrease the conductivity in BIT (Hong, 2000; Markovec, 2001; Shulman, 1999; Takenaka, 1981; Villegas, 1999; Zhang, 2004). Unfortunately, the piezoelectric effect in the high Curie temperature BIT is relatively low, with coefficient values typically less than 20 pC N⁻¹ found for both pure and modified Bi₄Ti₃O₁₂. Thus, it is a challenge to seek a rational pathway to improve the electrical property of BIT ceramics.
We have reported in our publications, the effects of composition and crystal lattice structure upon microstructure, dielectric, piezoelectric and electrical properties of BIT, Bi$_4$Ti$_3$-xW$_x$O$_{12}$+0.2wt\%Cr$_2$O$_3$ (BTWC), Bi$_4$Ti$_3$-xNb$_x$Ta$_x$O$_{12}$ (BTNT) and Bi$_4$Ti$_3$-xNb$_x$Ta$_{0.8}$Sb$_{0.2}$O$_{12}$ (BTNTS) ceramics have been widely investigated (Hou et al, 2009, 2010 and 2011). The processing of as-synthesized BIT were optimized and the main parameters were determined, and confirmed that the piezoelectric coefficient ($d_{33}$) of undoped BIT is 8 pC N$^{-1}$. As for BTWC, the results have shown the systematic changes in the lattice parameters; the formation of secondary phase(s) at higher levels of W/Cr doping; and the increase in dielectric constant and loss at room temperature with increase of doping content. A higher value of $d_{33}$, at 22 pC N$^{-1}$, was obtained for the sample with x=0.025, which may result directly from lowering conductivity. With regard to BTNT and BTNTS, the results have shown the formation of orthorhombic structure for all the samples within these family of dopants; the addition of Nb/Ta caused a remarkably suppressed grain growth while there is not much difference in grain size for BTNTS; as the doping content was increased, the Curie temperatures of BTNT decreased significantly, to as low as 630°C while the difference is not very significant for BTNTS. The co-doping at B-site could induce the distortion of oxygen octahedral and reduce the oxygen vacancy concentration, resulting in the enhancement of $d_{33}$. Especially, the highest values of 26 and 35pC N$^{-1}$, were obtained for Bi$_4$Ti$_{2.98}$Nb$_{0.01}$Ta$_{0.01}$O$_{12}$ and Bi$_4$Ti$_{2.98}$Nb$_{0.01}$Ta$_{0.002}$Sb$_{0.008}$O$_{12}$, respectively. The activation energy associated with the electrical relaxation and DC conductivity were determined from the electric modulus spectra, suggesting the movements of oxygen ions are possible for both ionic conductivity as well as the relaxation process. To ascertain the electrical conduction mechanism in the ceramics, various physical models have been proposed, suggesting the conductivity behavior of the ceramics can be explained using correlated barrier hopping model. All measurements demonstrated that BTNT ceramics are promising candidates for high temperature applications.

2. W/Cr modified Bi$_4$Ti$_3$O$_{12}$ ceramics

Bismuth titanate, Bi$_4$Ti$_3$O$_{12}$ (BIT) is a potential candidate for high-temperature device applications due to their high Curie temperature ($T_c$) and an excellent fatigue endurance property. However, the piezoelectricity of pure BIT ceramics is relatively very low ($d_{33} < 8$ pC N$^{-1}$). The piezoelectric properties can be enhanced by grain orientation techniques. However these methods are not cost effective. So, it is favourable to optimize piezoelectric properties via structural modification using appropriate doping. In this connection, to improve the piezoelectric properties of BIT, ions substitution with other cations have been considered and explored. It has been shown that doping with donor cations such as Nb$^{5+}$, V$^{5+}$ or Ta$^{5+}$ in the Ti$^{4+}$ positions decreases electrical conductivity and improves piezoelectric properties of BIT ceramics (Du, 2009; Shulman, 1999; Tang, 2007). Cr doping is another one of the most adopted strategies to tailor the dielectric and piezoelectric properties of ferroelectrics to practical specifications. It is well known that Cr is effective in decreasing the aging effect and decreasing dielectric loss thus the effect of doping of Cr$^{3+}$ is that of stabilizer of piezoelectric and dielectric properties (Li, 2008; Yang, 2007). The density of ceramics can be increased using small amount of Cr$_2$O$_3$. However, large content of Cr$_2$O$_3$ will inhibit grain growth because of accumulation of Cr$^{3+}$ at the grain boundary, which results in decrease in the grain size (Hou et al, 2005; Takahashi, 1970).
It is noted that the studies concerning the effect of $W^{6+}$ doping on electrical and sintering behavior have been reported earlier (Jardiel, 2006, 2008; Villegas, 2004). However, reports on W/Cr doped BIT ceramics are scarce. We have made an attempt to optimize the W/Cr doping to yield enhanced piezoelectric and dielectric properties of BIT ceramics. The influence of W/Cr doping on the structural, sintering behavior, dielectric, electrical conductivity and piezoelectric properties of BIT ceramics is reported in this section.

Fig. 1 (A) shows the X-ray diffraction patterns of BITWC ceramics at room temperature. Diffraction data does not show any evidence of the formation of tungsten and chromium oxide or associated compounds that contain bismuth or titanium. Therefore, the BITWC ceramics maintains a layer structure similar to the perovskite BIT even under extensive modifications by $W^{6+}/Cr^{3+}$.

Fig. 1. (A) XRD patterns of BITWC with different W/Cr content: (a) 0.0, (b) 0.025, (c) 0.05, (d) 0.075, (e) 0.10 and (f) 0.15. (B) Evolution of XRD patterns associated with the peaks of (020)/(200) and (220)/(1115) of BITWC powders with different W/Cr content.

Fig. 2. Variation in lattice parameters of BITWC powders calcined at 800 °C for 4 h vs. different amount of W/Cr doping.
Evolution of XRD patterns associated with the peaks of (020)/(200) and (220)/(1115) of BITWC with different W/Cr content are shown in Fig. 1 (B). For sample with 0.025W/Cr, the (020) diffraction pattern at $2\theta=33^\circ$ is clearly split into two (020) and (200) peaks in the orthorhombic phase thus the lattice constants $a \neq b$. With increasing W/Cr content, the splitting between the (020) and (200) peaks is decreased, indicating the reduction of the orthorhombicity $a/b$. When $x=0.05$, only the reflection (020) can be observed and the (020) reflections have shifted to higher $2\theta$ values, indicating a decrease in the lattice parameters $a$ and $b$ in the crystal structure. From Fig. 1 (B) the (220) reflections are observed to shift upwards in the orthorhombic form and the reflection (1115) is absent at $x=0.10$. That means the modification of tungsten and chromium for titanium ions distorts the positions of ions in the lattice, which may result from the different lattice strain relating to different ionic radius and outer electronic configuration between $W^{6+}$ and $Cr^{3+}$. As typically shown in Fig. 2, the decrease of the orthorhombic lattice parameters $a$ and $b$, and lattice volume $V$ of the BIT phase with an increasing amount of W/Cr doping are obvious, especially for the composition with W/Cr being less than 0.10. Further an increase in the amount of W/Cr to 0.15 does not cause a change of cell dimensions based on XRD results. However, no significant drop in lattice parameter, $c$, is found in BITWC powders calcined at 800 °C for 4 h. It is observed that the almost no volume change could be found for powders with W/Cr doping more than 0.10, allows us to further study the possibility of the formation of a second phase like $Bi_6Ti_3WO_{18}$ and $Bi_6Ti_5WO_{22}$ in the samples (Jardiel, 2008), although any secondary phases were not found by XRD techniques because of the limitation of XRD intensity below a certain concentration. A careful examination of the XRD patterns in Figs. 1

---

Fig. 3. SEM images of polished and thermal etched surfaces of various samples: (a) 0.025, (b) 0.05, (c) 0.075, (d) 0.10 and (e) 0.15. Scale represented in the figures is 3 μm.
(B) reveal that apart from the decrease of the lattice parameters and the difference between the a and b parameters, the peaks have broadened. The (1115) peaks in the patterns of x=0.10 and 0.15 appear as a weak shoulder on the right of the corresponding (220) peaks. Although the line-broadening of XRD peaks can have various origins, including grain size and dislocation structure (Snyder, 1999), it is expected that the observed line-broadening can be attributed to micro-strain in the material.

Fig. 3 shows the SEM images of the polished and thermally etched surfaces of BITWC ceramics. It is observed that the average grain size decreased with W/Cr doping ranging from approximately 10 μm to 1 μm, which suggest that W/Cr control the growth of the plate-like grains. It is reported that WO₃ influences the grain growth kinetics due to the slowing of grain boundary diffusion processes (Jardiel, 2008). The aspect ratio of the grains decreases with increase of W/Cr doping as shown in Fig. 3. This will lead to a better arrangement of the particles during the sintering processes and consequently to an enhanced densification of the ceramics. Table I shows the EDS analysis data of BITWC ceramics. When x ≤ 0.05, the experimentally observed atomic ratios agreed with the initial compositions signifies that the BITWC ceramics are single phase. This shows that the W⁶⁺/Cr³⁺ cations were incorporated into the layered perovskite structure and presumably occupied Ti⁴⁺ sites. While for x ≥ 0.075 compositions, EDS results were not in agreement with the initial theoretical atomic ratios. This indicates the presence of the secondary phases in the samples.

![Table 1](https://www.intechopen.com)
where $\tau$ is the relaxation time and $0 < \beta \leq 1$ is the parameter which indicates the deviation from Debye-type relaxation. The dielectric behaviour of the present ceramics is rationalized by invoking modified KWW function suggested by Bergman (Bergman, 2000). The imaginary part of the electric modulus ($Z'$) can be defined as:

$$\frac{Z'}{Z'_{\text{max}}} = \frac{1}{(1-\beta) + \frac{\beta}{1+\beta} \left[ \beta \left( \frac{f_{\text{max}}}{f} \right) + \left( \frac{f}{f_{\text{max}}} \right)^{\beta} \right]}$$

where $Z'_{\text{max}}$ is the peak value of the $Z'$ and $f_{\text{max}}$ is the corresponding frequency. Theoretical fit of Eq. 2 to the experimental data is shown in Fig. 4 (b) as the solid lines. It is seen that the experimental data are well fitted to this model except in the low frequency regime which may be due to electrode effect associated with the samples. From the fitting of $Z'$ versus frequency plots, the value of $\beta$ was determined and found to be temperature independent. The value of $\beta$ is found to be 0.82±0.02 in the 400-600 °C temperature range. Eq. 2 can be fitted for other compositions under study which are not shown in Fig. 4.

Fig. 4 depicts the variation of relaxation frequency with an inverse of absolute temperature for the composition of $x=0.025$. The activation energy for electrical relaxation can be calculated using Arrhenius relation as:

$$f_{\text{m}} = f_0 \exp \left( \frac{-E_a}{kT} \right)$$

where $f_0$ is the pre exponential factor, $k$ is the Boltzmann constant, and $T$ is the absolute temperature. Activation energy was calculated from the linear fit of the experimental data as shown in Fig. 5 for $x=0.025$ samples. Activation energy was estimated for the other compositions under study and the plot for activation energy versus composition is shown in the inset of Fig. 5. The activation energy increases with the W/Cr content, which suggests a decrease of oxygen vacancy concentration (Coondoo, 2007).
Fig. 5. Arrhenius plot for relaxation frequency versus temperature and inset shows variation of activation energy with $x$.

Table 2. Cole-Cole fitted parameters for the $x=0.025$ samples

If we scale each $Z'$ with $Z'_{\text{max}}$ and each $f$ with $f_{\text{max}}$, the entire curves collapse into a single master curve as shown in the Fig. 6 for $x=0.025$ samples. The scaling nature of $Z'$ implies that the relaxation shows the same mechanism in the entire temperature range. Similar behaviors were also observed for the other compositions ($x = 0.05, 0.075, 0.1$ and $0.15$) under study which are not shown here in the figure.

Figs. 7 depict complex impedance plots at 600 °C temperatures for $x=0.025$ samples. The complex impedance plots were resolved with two depressed semicircles corresponding to grain and grain boundaries. The impedance data for $x=0.025$ samples were fitted using superimposition of two Cole-Cole expressions as:

$$Z' = \frac{R_1}{1+(i\omega \tau_1)^{n_1}} + \frac{R_2}{1+(i\omega \tau_2)^{n_2}}$$

(4)

where $R_1$, $R_2$, $\tau_1$ and $\tau_2$ are resistance and relaxation times from grain and grain boundaries, respectively. The factors $n_1$ and $n_2$ indicate poly-dispersive multi Debye type relaxation. If the values are unity then the relaxation is explained by Debye type response. Experimental data were fitted using the software “ZsimpWin” as shown in Fig 7(a-d). The electrical contribution of the grains and grain boundaries was introduced by using an equivalent circuit as shown in inset of Fig 7(a). The results show the well-fitted impedance plots to the
Fig. 6. Scaling behaviour of $Z'$ at various temperatures.

Fig. 7. Cole-Cole plots for $x=0.025$ BITWC samples at various temperatures.
experimental data. The capacitors in the equivalent circuit are universal capacitors \((C = A(iio)^{-1})\), as introduced by Jonscher (Jonscher, 1977). Fitted parameters are reported in the Table II.

In order to study the relaxation mechanism for various compositions, the plots of \((Z'/Z'_{max})\) versus \(ff_{max}\) are shown in Fig. 8 for the compositions under study at 600 °C. It is to be noted that relaxation peaks are completely overlapped. This indicates that the relaxation mechanism is invariant with W/Cr content. However, the plots have not merged in the lower frequency regime. It is due to the extrinsic phenomenon associated with the samples.

![Scaling plots for various values of x at a temperature of 600°C.](image)

Dielectric constant and dielectric loss were calculated at various frequencies and temperatures (for the compositions under study) from the impedance data using the following relations:

\[
\varepsilon' = \frac{-Z'}{\omega C_o \left( Z^2 + Z'^2 \right)}
\]

\[
\tan \delta = \frac{Z'}{-Z}
\]

where \(C_o\) is the equivalent vacuum capacitance (= \(\varepsilon_o A / t\) of the sample. \(A\) and \(t\) are area and thickness of the sample. Fig. 9 shows the dielectric permittivity and dielectric loss (tan\(\delta\)) of W/Cr-doped BIT as a function of temperature measured at a frequency of 100 kHz. The dielectric peaks occur when the temperature is higher than 640 °C, which corresponds to the Curie temperatures. The Curie temperatures of BITWC are found to be slightly lower than that of BIT ceramic, and gradually decreased from 675 to 640 °C with increasing W/Cr content, which may partially arise from the difference of ionic radii (W\(^{6+}\): 0.62 Å, Cr\(^{3+}\): 0.52 Å, and Ti\(^{4+}\): 0.605 Å) and partially result from a decrease in the lattice distortion (Kan, 2004; Lopatin, 1989; Nagata, 2004; Villegas, 2004). A small hump is observed in temperature dependence dielectric constant plots for higher compositions of BITWC ceramics (x > 0.075).
(as shown in inset of Fig. 9). This may be due to the presence of secondary phase in the ceramics (Hyatt, 2005; Luo, 2001). There is a sudden increase of loss (tan δ) in the curve, with a peak position slightly below the $T_c$. After the $T_c$, the loss (tan δ) reaches a minimum value and then begins to increase once again. This dielectric loss valley is corresponding to the dielectric peak, i.e., the Curie temperature. The selected room temperature properties of BITWC ceramics are characterized and listed in Table III. With increasing of W/Cr contents, the Curie temperature and the dielectric loss decreased whilst the dielectric permittivity and loss vary sluggishly.

Fig. 9. Temperature dependence of dielectric constant and loss for the BITWC ceramics on W/Cr content.

In order to further elucidate the transport mechanism in the present ceramics, the electrical conductivity at different temperatures is studied. Electrical conductivity can be calculated from the dielectric data as:

$$\sigma(\omega) = \omega \varepsilon_0 \varepsilon'_1 \cdot \tan \delta$$

where $\omega$ is the angular frequency and $\varepsilon_0$ is the vacuum permittivity. Fig. 10 shows the frequency dependent (0.1 Hz-3 MHz) electrical conductivity at various temperatures for 0.025BITWC. Similar trends were found for other samples which are not mentioned in here Fig. 10. The electrical conductivity depends on frequency according to the “universal dynamic response” and can be related as $\sigma(\omega) = \sigma_{DC} + A \omega^n$, where $A$ is the temperature dependent parameter and the exponent $n$ is a characteristic parameter representing the many body interactions of the electrons, charges and impurities. It varies from 0 to 1 and for ideal Debye type behaviour it is equal to 1 (Jonscher, 1977). In Fig. 10, at all the
temperatures, the conductivity is independent of frequency at low frequency regime. Above a characteristic frequency, the conductivity increases with increase in frequency with characteristics $\omega^n$ dependence. The conductivity increases with increasing temperature due to thermal activation of conducting species in the samples. The frequency response of the other compositions also behaved similarly. Electrical conduction in BITWC ceramics is expected to result mainly from the defects presented in the lattice. These defects could come from the volatilisation of Bi$_2$O$_3$ during sintering, which could result in oxygen and bismuth vacancies. The variation of dc conductivity ($\sigma_{DC}$) with temperature can be described by Arrhenius equation as;

$$\sigma_{DC} = \sigma_o \exp\left(-\frac{E_{DC}}{kT}\right)$$

(8)

Where $\sigma_o$ is pre-exponential factor and $E_{DC}$ is activation energy associated with dc conductivity. Fig. 11 shows dc conductivity as a function of inverse of absolute temperature. From the slope of the linear fit, we can estimate activation energy associated with dc conduction. The variation of the activation energy with the W/Cr (x) content is depicted in the inset of Fig. 11. The activation energy (0.9 eV) for the conductivity of $x=0.025$ samples suggested an extrinsic conduction mechanism. With increasing W/Cr doping, the activation energy increased from ~0.9 to ~1.5 eV. This is associated with a change from extrinsic to intrinsic conductivity (Takahashi, 2003; Zhou, 2006; Zhang, 2009). It is well known that the intrinsic electronic conductivity activation energy is equal to half of the energy of the band gap ($E_g$). The reported value for the band gap is 3.3 eV for Bi$_4$Ti$_3$O$_{12}$ ceramics (Ehara, 1981) which is in close agreement with that of the present results (1.5 eV). It is interesting to note that the values for activation energy of dc conduction and electrical relaxation (Fig. 5) are in close agreement which indicates that the same ions are responsible for the both the processes (dc conduction and relaxation).

Fig. 10. Frequency dependent electrical conductivity at various temperatures.
Fig. 11. Arrhenius plot for dc conductivity for $x=0.025$ sample and inset shows variation of activation energy with W/Cr content.

Fig. 12. Frequency dependent electrical conductivity for various W/Cr content

To further investigate the conductivity for all the compositions, we have plotted frequency dependent (0.1Hz-3MHz) electrical conductivity for all the compositions under study at 600 °C temperature as shown in Fig. 12. It is interesting to note that electrical conductivity of $x=0.025$ sample decreases significantly as compared with that of undoped BIT ceramics. Consequently conductivity increases with further increase in W/Cr content. In BIT ceramics, hole compensation of bismuth vacancies promotes $p$-type electronic conductivity. Under charge neutrality restriction, when $W^{6+}$ substitutes $Ti^{4+}$, two positive charge centers at W site
and two electrons will be created. These electrons neutralize the influence of the holes. The conductivity decreases with donor doping to a minimum value where the concentration of electron holes matches the electron concentration \( (p=n) \). With a further increase in the donor \( (W^{6+}) \) concentration the conductivity becomes \( n \)-type and starts to increase again. The minimum conductivity appears at a lower \( W/\text{Cr} \) content doped BIT ceramics \( (x=0.025) \). Presence of secondary phase in higher concentration doped \( (x>0.075) \) ceramics can also play crucial role in the conductivity behaviour (Hyatt et al. 2005; Jardiel et al. 2006). It is reported that the Bi\(_3\)Ti\(_3\)WO\(_{13}\) ceramics have higher conductivity than Bi\(_4\)Ti\(_3\)O\(_{12}\) ceramics which results higher conductivity associated with the ceramics of higher concentration \( (x > 0.075) \). However, it is reported in the literature that the conductivity decreases up to concentration of \( x = 0.08 \) and consequently increases in sluggish manner with increase in the \( W \) doping (Jardiel, 2008). The reported value of dc conductivity at 600 °C is \( 3.2 \times 10^{-5} \) (ohm cm)\(^{-1} \) for the \( W \) doping concentration of 0.05 (Jardiel, 2008). While in the present investigations, the value of dc conductivity is found to be \( 2.38 \times 10^{-6} \) (ohm cm)\(^{-1} \) for the \( x=0.05 \) \( W/\text{Cr} \) doping at 600 °C. This difference in the value of electrical conductivity can be attributed to microscopic heterogeneity and random arrangement of cations in the structure due to the presence of Cr ions along with \( W \) and Ti ions at B-site. The interaction between the cations controls the conduction and dielectric mechanisms of the present ceramics. A defect chemistry expression for \( W \) doping can be written as

\[
\text{WO}_3 + V_{o}\leftrightharpoons \frac{1}{2} \text{TiO}_2 \rightarrow 0.5 \text{W}^{5+} + 3O_{o}
\]

It shows that the oxygen vacancies are reduced upon the substitution of donor \( W^{6+} \) ion for \( \text{Ti}^{4+} \). Hence, it is reasonable to believe that the conductivity in BIT ceramics is suppressed by donor doping.

The piezoelectric constant \( (d_{33}) \) was measured at room temperature for all the compositions. All the samples were electrically poled prior to piezoelectric measurements. It is interesting to observe that the sample for \( x=0.025 \) has higher \( d_{33} \) coefficient than that of the other compositions (Table III). It is related to the fact that composition corresponding to \( x=0.025 \) has lowest conductivity among the samples studied in this work and thus allowing for better poling. The gained increment in \( d_{33} \) by \( W/\text{Cr} \) co-doping is very desirable, indicating a significant improved piezoelectric property due to \( W/\text{Cr} \) modification.

Table 3. Physical characteristics for \( W/\text{Cr} \) modified BIT ceramics at room temperature.

The crystallographic evolution and phase analysis of \( \text{Bi}_4\text{Ti}_3\text{O}_{12}:W/\text{Cr} \) ceramics were determined by the XRD and the microstructural morphology was studied by SEM analysis.
The modification of W/Cr significantly improved the piezoelectric activity of the Bi$_4$Ti$_3$O$_{12}$:W/Cr ceramics. The Curie temperature decreased slightly with W/Cr modification increasing. Electrical relaxation mechanism was found to be similar for all the compositions. The excellent piezoelectric and dielectric properties coupled with high Curie temperature, demonstrated that the Bi$_4$Ti$_{12.975}$W$_{0.025}$O$_{12.025}$+0.2wt%Cr$_2$O$_3$ (x=0.025) ceramics are promising candidates for high temperature applications.

3. Nb/Ta modified Bi$_4$Ti$_3$O$_{12}$ ceramics

Doped BIT is of interest in high-temperature piezoelectric sensors, because it remains ferroelectric at T > 600 °C and offers relatively high piezoelectric property (Kumar, 2001; Nagata, 1999; Noguchi, Sugibuchi, 1975; Shimakawa, 2000; Subbarao, 1961; 2000; Shulman, 2000; Shimazu, 1980). High leakage current and domain pinning due to defects in undoped BIT have appeared as obstacles for further applications. Unfortunately, the piezoelectric effect in high Curie temperature BIT is relatively low, with coefficient values less than 10 pC N$^{-1}$ for pure BIT and less than 20 pC N$^{-1}$ for modified Bi$_4$Ti$_3$O$_{12}$. To improve the piezoelectric property, Nb/Ta co-modified BIT ceramics were fabricated by a conventional solid-state reaction process and the influence of the Nb$_2$O$_5$/Ta$_2$O$_5$ additive on the structure and electrical properties of the ceramics was investigated. The composition Bi$_4$Ti$_{3-2x}$Nb$_x$Ta$_x$O$_{12}$ (BTNT, x=0, 0.01, 0.02, 0.04, 0.06) polycrystals were prepared by the conventional solid-state reaction technique.

To investigate the effect of Nb/Ta modified BIT ceramics on the phase stability, Bi$_4$Ti$_{3-2x}$Nb$_x$Ta$_x$O$_{12}$ powders calcined at 800 °C for 4 h were prepared and their crystal structures were analyzed using XRD. Fig. 13 shows the XRD patterns of all samples. Diffraction data does not show any evidence of the formation of niobium and tantalum oxides or associated compounds that contain bismuth or titanium. This observation indicates that Nb/Ta ions in the BTNT ceramics do not form minority phase or segregate from the interior grain but dissolve into the perovskite lattice. Therefore, the BTNT ceramics maintains a layer structure similar to the perovskite BIT.

Fig. 13. XRD patterns of Bi$_4$Ti$_{3-2x}$Nb$_x$Ta$_x$O$_{12}$ powders calcined at 800 °C for 4 h on different Nb/Ta amounts.
The microstructures of BTNT ceramics are shown in Fig. 14. As figure 14 show, the average grain size ranging from approximately 40 μm to 1μm in length decreased with increase of Nb/Ta amount, which suggested that the additive controlled the growth of the plate-like grains. The porosity was mainly located on grain boundaries. As is well known, both sintering and grain growth are closely associated with ion migration. Thus if the incorporation of Nb$^{5+}$/Ta$^{5+}$ into BIT led to an increase in the activating energy for ion migration, a reduction in the rate of grain growth would be expected with increasing amounts of Nb/Ta. Furthermore, according to the sintering theory, the particle surface energy and grain boundary energy are the major driving forces for sintering and grain growth.

BTNT ceramics sintered at the temperatures giving maximum density values were used for the measurement of dielectric property. Fig. 15 shows the permittivity, ε$, and dielectric loss, tanδ, of Nb/Ta-doped BIT ceramics as a function of temperature measured at a frequency of 100 KHz. The Curie temperatures of BTNT ceramics are found to be slightly lower than that of BIT ceramic, and gradually decreased from 675 to 630 °C with increasing Nb/Ta amounts due to the contribution of space charge and ionic motion (Fouskova, 1970). Moreover, the phase transition peaks become broad and diffusive, which may result from the cation-exchange between Ti$^{4+}$ in TiO$_6$ octahedra and Nb$^{5+}$/Ta$^{5+}$ at the B sites to release the misfit strain due to the similar ionic radii (Nb: 0.69 Å, Ta: 0.64 Å, Ti: 0.605 Å). For the dielectric
loss, there is a sudden increase in the curve, with a peak position slightly below the Curie temperature, $T_c$. After the $T_c$, the dielectric loss reaches a minimum value and then begins to increase once again. With increasing Nb/Ta amounts the peaks of the dielectric loss shifted to the lower temperature and even became flatter. So the activation energy of oxygen vacancy correspondingly increased with the distortion of lattice after doping enhances its hopping barrier. It is clear that the introduction of the Nb$^{5+}$/Ta$^{5+}$ at B-site in BIT as donor impurities can effectively reduce the oxygen vacancies, which may be elucidated by the defect reaction:

$$Nb_2O_5 + V_O^T \rightarrow 2Nb_{Tl}^T + 5O_2^T \quad \text{and} \quad Ta_2O_5 + V_O^T \rightarrow 2Ta_{Tl}^T + 5O_2^T. \quad (10)$$

A decrease of the oxygen vacancy after the Nb$^{5+}$/Ta$^{5+}$ doping results in the depression of the dielectric loss peak, which was consistent with previous reports (Shulman, 2000, 1996; Villegas, 1999). Thus B-site doping of equal valence can screen the effect of oxygen vacancy, which is contributing to an enhancement of the dielectric property of BTNT ceramics.

Fig. 15. Temperature dependence of permittivity and dielectric loss for BTNT ceramics on Nb/Ta amounts.
The selected room temperature properties of BTNT ceramics as a function of Nb/Ta amounts are characterized. Fig. 16c shows the permittivity and dielectric loss of the BTNT ceramics as a function of Nb/Ta amount. It was found that the room temperature permittivity of BTNT ceramics increased drastically whilst the dielectric loss decreased due to the depression of the oxygen vacancies with increasing Nb/Ta amounts. Figure 16a and 16b show the piezoelectric coefficient \( d_{33} \) and Curie temperature \( T_c \) of the BTNT ceramics for varying amounts of Nb/Ta. The \( d_{33} \) values first increased and reached a maximum value of 26 pC N\(^{-1}\) for samples with \( x=0.01 \). However, previous research has shown that doping a small amount of Nb\(_2\)O\(_5\) or Ta\(_2\)O\(_5\) resulted in an increase in the \( d_{33} \) from 8 to 20 pC N\(^{-1}\) (Shulman, 1996, Shulman, 2000). The gained increment in \( d_{33} \) by Nb/Ta co-doping is very desirable, indicating a significant improvement in the piezoelectric property. The change in piezoelectric properties was explained with a grain size effect, namely, a sound grain growth with the addition of Nb\(_2\)O\(_5\)/Ta\(_2\)O\(_5\) enables a consummate development of ferroelectric domains and thus improves the piezoelectric properties. As a result, there may be more crystallographic directions suitable for polarization, facilitating piezoelectricity. Based on decreasing dielectric loss, it’s proposed that the grain size effects play a dominant role in the piezoelectric response. On the other hand, with decrease in oxygen vacancies diffusing to the domain wall in bulk, the pinning of the domain wall can decrease and the number of available switching domain walls can increase, resulting in enhancement of the \( d_{33} \). But a further increase of concentration of Nb/Ta in BIT could act as pinning centres for domain walls and reduce their contribution to the piezoelectric effect, which is consistent with the previous reports that the addition of Nb and other cations in perovskite layer with dimensional mismatch between perovskite and bismuth oxide layers (Armstrong, 1972). It also can be seen the Nb/Ta doping causes more drastic decrease in the values of \( T_c \). Thermal annealing behavior for the control and Nb/Ta modified BIT ceramics are shown in Figure 16d, where the piezoelectric coefficient, \( d_{33} \) are plotted against the annealing temperature. The values of \( d_{33} \) of the BTNT ceramics show no obvious drop, when the annealing temperature is lower than 500 °C. This reveals that BTNT orthorhombic structured materials are very stable to thermal annealing. When annealing temperature is higher than 500 °C, about 74 % of \( T_c \), the piezoelectric coefficient of all BTNT ceramics decreases sharply, and tends to zero when the annealing temperature is above \( T_c \).

The B-site vacancies Bi\(_{4}\)Ti\(_{3-2x}\)Nb\(_x\)Ta\(_x\)O\(_{12}\) ceramics were synthesized by the solid-state reaction process. The analysis of the structure and the morphology were performed by XRD and FESEM. All the specimens maintained the orthorhombic structure and the addition of Nb\(_2\)O\(_5\)/Ta\(_2\)O\(_5\) caused a remarkably suppressed grain growth, which plays the dominant role in the piezoelectric response. This work also presented the considerable influence of Nb\(_2\)O\(_5\)/Ta\(_2\)O\(_5\) additive on the dielectric and piezoelectric properties. The Curie temperature, \( T_c \), decreased from 675 to 630 °C while the permittivity increased drastically. The Nb/Ta doping at B-site could induce the distortion of oxygen octahedral and reduce the oxygen vacancy concentration by the compensating effect which is contributed to the enhancement of piezoelectric activity. The high piezoelectric coefficient \( d_{33} \) of Bi\(_4\)Ti\(_{2.98}\)Nb\(_{0.01}\)Ta\(_{0.01}\)O\(_{12}\) ceramics controlled by precisely optimizing Nb/Ta amounts is found to be 26 pC N\(^{-1}\). All measurements demonstrated that BTNT ceramics are the promising candidates for high temperature applications.
4. Nb/Ta/Sb modified Bi$_4$Ti$_3$O$_{12}$ ceramics

Lead-based piezoelectric ceramics such as Pb(Zr,Ti)O$_3$ (PZT), are widely used in piezoelectric actuators, sensors, and transducers due to their high relative permittivity, large remnant polarization, and excellent piezoelectric coefficients (Jaffe, 1971; Uchino, 2000). However, evaporation of toxic lead oxides during high temperature sintering produces environmental toxic burden and also generates instability of the composition and electrical properties of the ceramics. Thus, investigation of the possible use of ecologically clean lead-free ceramics in the field of science and technology is of great interest.

Bismuth titanate, Bi$_4$Ti$_3$O$_{12}$ (BIT) is considered to be an excellent candidate as a key lead-free piezoelectric material owing to promising piezoelectric and ferroelectric properties. It is also a promising material for high temperature piezoelectric applications because of the high Curie temperature. However, as the spontaneous polarization movements are restricted to the $ab$ plane of the unit cell (the $c$-axis component can be neglected), the ferroelectric and piezoelectric properties are much lower than those of PZT materials. It is likely, the piezoelectricity of pure BIT ceramics is low ($d_{33} < 8$ pC N$^{-1}$), due to the fact that it has high electrical conductivity and high coercive field which impedes the poling process (Ahn, 2009; Hou, 2010; Shulman, 2000, 1996; Villegas, 2004). The piezoelectric properties can be enhanced by grain orientation techniques (Jones, 2005; Zhang, 2005). However, these
processing methods such as hot forging or tape casting methods are not as cost effective as the production of ceramics via traditional powder pressing technologies. So, it is favourable to optimize piezoelectric properties via structural modification using appropriate doping. In this context, cations substitution to improve the piezoelectric properties of BIT have been considered and explored. It has been shown that the doping with donor cations such as Nb\(^{5+}\), W\(^{6+}\) or Ta\(^{5+}\) in the Ti\(^{4+}\) positions decreases electrical conductivity and improves piezoelectric properties of BIT ceramics (Azurmendi, 2006; Hou et al, 2010; Hong, 2000). We have reported that the value of \(d_{33}\) was 26 pC N\(^{-1}\) for Nb/Ta doped BIT ceramics, fabricated via the conventional solid state reaction route (Hou, 2009).

It is noted that the studies concerning the effect of Sb doped lead-free piezoelectric ceramics have been reported earlier, exhibiting high-performance piezoelectric and dielectric properties (Saito, 2004; Zhao, 2008; Zhang, 2010). However, reports on Sb-doped BIT ceramics are scarce. To further study the piezoelectric property, Sb\(_2\)O\(_3\) has been considered for modifying Bi\(_4\)Ti\(_3\)-2xNb\(_x\)Ta\(_x\)O\(_{12}\) (BTNT) ceramics via the conventional solid-state reaction route. The influence of the Sb\(_2\)O\(_3\) additive on the structural, morphological, dielectric, electrical conductivity and piezoelectric properties of the ceramics is investigated in this work.

Fig. 17 shows XRD patterns of BTNTS powders calcined at 800 °C for 4 h. The XRD analysis of BTNTS ceramic powders revealed the presence of BTNTS phase. Therefore, the BTNTS ceramics in the Sb substituted structure can maintain a layer perovskite structure similar to the parent BIT perovskite.

The microstructures of BTNTS ceramics are shown in Fig. 18. The average grain size can be observed to be varying with the content of Sb\(_2\)O\(_3\), suggesting that the additive controlled the growth of the plate-like grains of BTNTS. 8BTN TS ceramic has slight larger grains while there is a small variation in grain size for the other samples. Change in the microstructure with doping content is due to the reported formation of liquid phase (sillenite phase) which is generally observed during the synthesis of BIT (Rojero et al. 2010) (Although, this secondary phase was not detected in XRD due to small amounts (Fig. 17)). This liquid phase is increasing

![XRD patterns](image-url)
with the increase in Sb$_2$O$_3$ content and avail grain growth. 8BTNTS ceramic has larger grain size due to the presence of larger quantity of sillenite phase. However 10BTNTS ceramic samples were observed with smaller grains (Fig. 18(f)). It may be due to excess amount of antimony (after formation of solid solution) which reacted with sillenite phase and reduced it.

Fig. 18. SEM images of BTNTS ceramics with different Sb$_2$O$_3$ content: a) 0BTNTS, b) 2BTNTS, c) 4BTNTS, d) 6BTNTS, e) 8BTNTS, f) 10BTNTS

Fig. 19. Piezoelectric coefficients ($d_{33}$) of BTNTS ceramics with different Sb$_2$O$_3$ content at room temperature (a), comparison of $d_{33}$ among 8BTNTS and BIT family (b) (BIT, BIT-W, BIT-Ta BIT-Nb, BIT-V, BIT-Nb/Ta)

Fig. 19 shows the variation of the piezoelectric coefficient ($d_{33}$) with respect to the content of Sb$_2$O$_3$ for the BTNTS ceramics. The value of $d_{33}$ was found to be highest (35 pC N$^{-1}$) for 8BTNTS ceramics. The $d_{33}$ value is lower with deviation from 8BTNTS composition in both directions of increasing or decreasing the content of Sb$_2$O$_3$, but in all other compositions from 0 to 8, exceeds the hitherto maximum value of ~20 pC N$^{-1}$. The $d_{33}$ (35 pC N$^{-1}$) of
8BTNTS is 337.5%, 84.2%, 75% and 34.6% higher than that of BIT (Shulman, 1996), W-doped BIT (Zhang, 2004), V-doped BIT (Tang, 2006), Nb-doped BIT (Shulman, 2000), Ta-doped BIT (Hong, 2000), and Nb/Ta-doped BIT (Hou et al, 2009). The thermal annealing behaviors for the 0BTNTS, 8BTNTS and 10BTNTS ceramics are shown in Fig. 20, where the piezoelectric coefficient, $d_{33}$, are dependent on the annealing temperature. The $d_{33}$ values of the BTNTS ceramics show no obvious drop, when the annealing temperature is lower than 500 °C. This indicates that BTNTS monoclinic structured materials are very stable to thermal annealing. When annealing temperature is higher than 500 °C, the piezoelectric coefficients of the 0BTNTS, 8BTNTS and 10BTNTS ceramics decrease sharply, and tend to zero when the annealing temperature is above Curie temperature (675 °C). No obvious degradation of the 0BTNTS, 8BTNTS and 10BTNTS ceramics is observed below 500 °C.

![Fig. 20. Effect of annealing temperature for 2 h on $d_{33}$ for 0BTNTS, 8BTNTS and 10BTNTS ceramics](image)

![Fig. 21. Temperature dependence of permittivity for Bi$_4$Ti$_{2.98}$Nb$_{0.01}$Ta$_{0.002}$Sb$_{0.008}$O$_{12}$ ceramics at 100 kHz and 1 MHz](image)

www.intechopen.com
It is well known that the electrical properties are of fundamental importance for the piezoelectric applications. It is therefore worthwhile to investigate these properties over a moderately wide frequency and temperature range for 8BTNTS samples (highest $d_{33}$ value among the Bi$_4$Ti$_3$O$_{12}$-based ceramics). Fig. 21 shows the permittivity, $\varepsilon_r$, of Bi$_4$Ti$_{2.98}$Nb$_{0.01}$Ta$_{0.002}$Sb$_{0.008}$O$_{12}$ ceramics as a function of the temperature measured at 100 KHz and 1 MHz. Two peaks are observed at around 600 °C and 660 °C (at both frequencies (100 KHz and 1 MHz)) corresponding to the phase transformation of secondary and 8BTNTS phases, respectively. To confirm our results, the differential scanning calorimetric trace for 8BTNTS ceramics is depicted in Fig. 22. The sharp peak at 664 °C is associated with the phase transformation and ascribed as a Curie temperature which is in close agreement with that of the permittivity versus the temperature plots (Fig. 21). Though, another peak (600 °C) was not detected in DSC trace.

Fig. 22. DSC curve of Bi$_4$Ti$_{2.98}$Nb$_{0.01}$Ta$_{0.002}$Sb$_{0.008}$O$_{12}$ ceramic

Fig. 23 depicts the frequency dependent (0.1 Hz ~3 MHz) electrical conductivity for all the compositions at 600 °C. It is interesting to note that the electrical conductivity of 8BTNTS decreases significantly as compared with that of other ceramics. This difference in the value of electrical conductivity may be attributed to microscopic heterogeneity and random arrangement of cations in the structure due to Sb/Nb/Ta/Ti ions at B-site. We have reported that addition of Nb and Ta can directly introduce additional electrons for neutralizing the effect of $p$-type conductivity commonly observed in pure BIT (Shulman, 1996). These dopants also decrease the concentration of oxygen vacancy in the BIT doped by Nb/Ta. Sb has 3+ oxidation state in Sb$_2$O$_3$ (0.76 Å ionic radii) and can not be fitted on Ti$^{4+}$ site (0.605 Å). However it is reported (Peiteado, 2006) that Sb$^{3+}$ is unstable above 500 °C and completely transform into Sb$^{5+}$ (0.60 Å ionic radii) in the presence of Bi$_2$O$_3$ oxide. It indicates that in the present study, Sb$^{5+}$ ions are accommodated at Ti$^{4+}$ sites since samples were sintered at 1100 °C. The amount of Sb added to the Nb/Ta doped BIT is in relatively small concentrations at the B-sites in the perovskite structure. In addition to the effect of reducing $p$-type conductivity, and decreasing oxygen vacancy concentration we can expect greater domain wall movement. Thus, Sb has the effect of controlling this switch to $n$-type conductivity while not impairing the decrease in $p$-type conductivity. In addition to donor
effect of antimony, it is noticed that the microstructures of these samples are also doping dependent (Fig. 18). Scanning electron micrographs (Fig. 18) show that 8BTNTS ceramics have larger grain size than that of the other investigated samples. It is reported that microstructure plays for electrical properties of BIT ceramics (Jardiel, 2006). Due to the decrease in electrical conductivity, the polarization is aided, facilitating the improved piezoelectricity. The possible explanation may be ascribed to decrease in the concentration of oxygen vacancies that can diffuse to domain walls in the piezoelectric ceramic, resulting in lowering the pinning of the domain walls, thus increasing the number of available switching domain walls and resulting in the enhancement of $d_{33}$ (Zhang, 2006).

![Electrical conductivity of BTNTS ceramics with different Sb$_2$O$_3$ content at 600 °C](image)

In order to understand the conductivity mechanism in BTNTS ceramics, the ac conductivity plots that were obtained in the 300~600 °C temperature range for the 8BTNTS ceramics are shown in Fig. 24. The conductivity increases with increasing temperature due to thermal activation of conducting species in the samples. It exhibits two relaxations at different frequency region. The low frequency relaxation can be attributed to the grain boundary. As the frequency increases, the grain boundary resistance might become less than that of grain and grains dominate conductivity. The resistance and capacitance associated with grain and grain boundary interplay between their capacitive and dielectric contributions depending upon the frequency range. The high frequency conductivity is entirely due to the hopping of localized charge carriers. The bulk DC conductivity is difficult to ascertain from the above data (Fig. 24) because of significant contributions of grain boundary to the conductivity in low frequency regime.

The electric modulus approach was invoked to elucidate the electrical transport mechanism in 8BTNTS ceramics. The physical nature of the electric modulus (Macedo, 1972) is used to make a correlation between the conductivity and the relaxation of ions in these materials. This approach can effectively be employed to study bulk electrical behaviour of the moderately conducting samples. The complex electric modulus ($M'$) is defined in terms of the complex dielectric constant ($\varepsilon^*$) and is represented as:

$$M' = (\varepsilon^*)^{-1}$$  \hspace{1cm} (11)
where $M'$, $M''$ and $\varepsilon_r$, $\varepsilon''_r$ are the real and imaginary parts of the electric modulus and dielectric constant, respectively. Effects of electrode polarization and the electrical conductivity can be suppressed using the electric modulus formalism. The real and imaginary parts of the modulus at different temperatures are calculated using Eq. 12 for the 8BTNTS ceramics and depicted in Figs. 25 (a) and 25 (b), respectively.

It is seen from Fig. 25 (a) that at low frequencies, $M'$ approaches zero at all the temperatures under study suggesting the suppression of electrode polarization effects. $M'$ reaches a maximum value corresponding to $M_{\infty} = (\varepsilon_r)^{-1}$ due to the relaxation process. It is also observed that the value of $M_{\infty}$ decreases with the increase in temperature. The imaginary part of the electric modulus (Fig. 25 (b)) is indicative of the energy loss under electric field. The $M'$ peak shifts to higher frequencies with increasing temperature. This suggests the involvement of temperature-dependent relaxation processes in the present ceramics. The frequency region below the $M'$ peak indicates the range in which ions drift to long distances. In the frequency range which is above the peak, the ions are spatially confined to potential wells and free to move only within the wells. The frequency range where the peak occurs is suggestive of the transition from long-range to short-range mobility of ions.

The relaxation time associated with the process was determined from the plot of $M'$ versus frequency. The activation energy involved in the relaxation process of ions can be obtained from the temperature dependent relaxation frequency ($f_{\text{max}}$) as:

$$f_{\text{max}} = f_0 \exp \left( - \frac{E_R}{kT} \right)$$  \hspace{1cm} (13)
Fig. 25. (a) Real and (b) imaginary parts of the electric modulus as a function of frequency at different temperatures for 8BTNTS ceramics.

Fig. 26. ln $(f_{\text{max}})$ versus $1000/T$ for 8BTNTS ceramics.
Fig. 27. $\ln(\sigma_{\text{DC}})$ versus $1000/T$ for 8BTNTS ceramics

where $E_R$ is the activation energy associated with the relaxation process, $f_0$ is the pre-exponential factor, $k$ is the Boltzmann constant and $T$ is the absolute temperature. Fig. 26 shows a plot between $\ln(f_{\text{max}})$ and $1000/T$ along with the theoretical fit (solid line) to the above equation (Eq. 13). The value that is obtained for $E_R$ is $1.00 \pm 0.03$ eV, which is ascribed to the motion of oxygen ions and is consistent with more reported in the literature. The value of activation energy for 8BTNTS ceramics is higher than that of activation energy reported for pure BIT (Uchino, 2000). An increase in the activation energy as compared to BIT is an indication of the reduction of oxygen vacancies in 8BTNTS ceramics. This is due to the fact that the hole compensation of bismuth vacancies promotes $p$-type electronic conductivity. When Sb$^{5+}$&Nb$^{5+}$&Ta$^{5+}$ ions substitute Ti$^{4+}$ and electrons will be created under charge neutrality restriction. These electrons neutralize the influence of the holes. The conductivity decreases with donor doping to a minimum value where the concentration of electron holes matches the electron concentration ($p = n$). With a further increase in the donor (Sb$^{5+}$&Nb$^{5+}$&Ta$^{5+}$) concentration the conductivity becomes $n$-type and starts to increase again.

The electric modulus can be expressed as the Fourier transform of a relaxation function $\phi(t)$:

$$M^* = M_0 \left[1 - \int_0^\infty \exp(-\omega t) \left( \frac{d\phi}{dt} \right) dt \right]$$

(14)

where the function $\phi(t)$ is the time evolution of the electric field within the materials and is usually taken as the Kohlrausch-Williams-Watts (KWW) function (Kohlrausch, 1954; Williams, 1970):

$$\phi(t) = \exp\left[ -\left( \frac{t}{\tau_m} \right)^\beta \right]$$

(15)

where $\tau_m$ is the conductivity relaxation time and the exponent $\beta$ ($0 < \beta < 1$) indicates the deviation from Debye type relaxation. The smaller the value of $\beta$, the larger is the deviation.
from Debye-type relaxation. When \( \beta \) is close to zero, there exists a strong correlation between the hopping ions and its neighbouring ions. The \( \beta \) was calculated at different temperatures using the electric modulus formalism. For the ideal Debye type relaxation, the full-width half maximum (FWHM) of imaginary part of electric modulus is 1.14 decades. Therefore, \( \beta \) can be defined as \( 1.14 / \text{FWHM} \). One can estimate DC conductivity at different temperatures using the electrical relaxation data. The DC conductivity can be expressed as (Ngai, 1984):

\[
\sigma_{DC}(T) = \frac{\varepsilon_0}{M_\infty(T)} \cdot \frac{\beta}{\Gamma\left(\frac{1}{\beta}\right)}
\]

(16)

where \( \varepsilon_0 \) is the free space dielectric constant, \( M_\infty(T) \) is the reciprocal of high frequency dielectric constant and \( \tau_m(T)/(1/2\pi f_{max}) \) is the temperature dependent relaxation time. This equation is applicable to a variety of materials with low concentrations of charge carriers (Takahashi, 2004; Vaish, 2009). Calculation for DC conductivity from AC conductivity formalism causes a large error (due to electrode effect) that can be circumvented from the electrical relaxation formalism. Fig. 27 shows the DC conductivity data obtained from the above expression (Eq. 16) at various temperatures. The activation energy for the DC conductivity was calculated from the plot of \( \ln(\sigma_{DC}) \) versus \( 1000/T \) for BTNTS ceramics, which is shown in Fig. 27. The plot is found to be linear and fitted using following the Arrhenius equation,

\[
\sigma_{DC}(T) = B \exp\left(\frac{E_{DC}}{kT}\right)
\]

(17)

where \( B \) is the pre-exponential factor and \( E_{DC} \) is the activation energy for the DC conduction. The activation energy is calculated from the slope of the fitted line and found to be 1.08 \( \pm \) 0.02 eV. This value for activation energy is in close agreement with the activation energy for
electrical relaxation. Fig. 28 represents the normalized plots of electric modulus $M'$ as a function of frequency wherein the frequency is scaled by the peak frequency. A perfect overlapping of all the curves on a single master curve is not found. This shows that the conduction mechanism changed with temperature which is in good agreement with that of reported in literature (Takahashi et al 2004). Takahashi et al. reported that BIT exhibits mixed (ionic-p-type) conduction at high temperature and ionic conductivity was larger than hole conductivity in Curie temperature range.

Fig. 29. The frequency dependence of (a) the dielectric constant and (b) loss at various temperatures for 8BTNTS ceramics. It is evident that at all the temperatures (Fig. 29(a)), the value of $\varepsilon'$ decreases with increasing frequency and attains a constant value. The high value of the dielectric constant in low-frequency regions is an extrinsic phenomenon arising due to the presence of metallic or blocking electrodes which do not permit the mobile ions to transfer into the external circuit, and as a result, mobile ions pile up near the
electrodes and give a large bulk polarization in the materials as well as oxygen ion polarization at grain boundaries. When the temperature rises, the dispersion region shifts towards higher frequencies and the nature of the dispersion changes at low frequencies due to the electrode polarization along with grain boundary effects. A plateau region at 500 °C was observed at moderately low frequencies that shifted to higher frequencies with increase in temperature (600 °C). This plateau region distinguished electrode polarizations to the grain boundary polarizations. The variation in the tanδ with the temperature at various frequencies (Fig. 29(b)) is consistent with that of the dielectric behaviour. The loss decreases with increase in frequency at different temperatures (300-600 °C). It is also observed that the dielectric loss increases with increase in temperature which is attributed to the increase in conductivity of the ceramics due to thermal activation of conducting species. The clear relaxation peak was not encountered at any temperature under study because of dominant DC conduction losses due to high oxygen ion mobility in the temperature range under study.

5. Conclusions
We have reported the effects of composition and crystal lattice structure upon microstructure, dielectric, piezoelectric and electrical properties of BIT, Bi$_4$Ti$_3-x$W$_x$O$_{12+x}$+0.2wt%Cr$_2$O$_3$ (BTWC), Bi$_4$Ti$_3-x$Nb$_x$Ta$_x$O$_{12}$ (BTNT) and Bi$_4$Ti$_3-x$Nb$_x$Ta$_x$Sb$_y$O$_{12}$ (BTNTS) ceramics. We have shown how doping can increase the piezoelectric coefficient of BIT. For the W/Cr samples, a $d_{33}$ coefficient of 22 pC N$^{-1}$ was measured for $x=0.025$. The piezoelectric coefficient $d_{33}$ of Bi$_{3.98}$Ta$_{0.01}$Nb$_{0.01}$O$_{12}$ ceramics controlled by precisely optimizing Nb/Ta amounts is found to be 26 pC N$^{-1}$. The highest room temperature value of the piezoelectric coefficient is found to be 35 pC N$^{-1}$ for 8BTNTS ceramics. The antimony incorporation into the BTNT ceramics controlled electrical conductivity through reduction in the ionic and electronic conductivities as well as altered microstructure. The activation energy associated with the electrical relaxation determined from the electric modulus spectra was found to be $1.0 \pm 0.03$ eV, close to that of the activation energy for DC conductivity ($1.08 \pm 0.02$ eV). It suggests that the movements of oxygen ions are responsible for both ionic conduction as well as the relaxation process. These results demonstrated that 8BTNTS ceramic is a promising candidate for high temperature piezoelectric applications.

Ferroelectric materials have been and still are widely used in many applications, that have moved from sonar towards breakthrough technologies such as memories or optical devices. This book is a part of a four volume collection (covering material aspects, physical effects, characterization and modeling, and applications) and focuses on the underlying mechanisms of ferroelectric materials, including general ferroelectric effect, piezoelectricity, optical properties, and multiferroic and magnetoelectric devices. The aim of this book is to provide an up-to-date review of recent scientific findings and recent advances in the field of ferroelectric systems, allowing a deep understanding of the physical aspect of ferroelectricity.
