Air Pollution and Primordial Prevention of Chronic Non-Communicable Diseases

Parinaz Poursafa¹ and Roya Kelishadi²

¹Environment Research Center, Isfahan University of Medical Sciences, Isfahan, Iran
²Child Health Promotion Research Center, Isfahan University of Medical Sciences, Isfahan, Iran

1. Introduction

Air pollution is a global health issue with serious public health implications particularly for children. Studying the effects of environmental factors on the early stages of atherosclerosis can serve for future studies and offer strategies for primary prevention of chronic disease. Usually respiratory effects of air pollutants are being considered, this chapter highlights the importance of non-respiratory health hazards from early life. In addition to short-term effects, exposure to criteria air pollutants from early life might be associated with low birth weight, increase in stress oxidative and endothelial dysfunction which in turn might have long-term effects on chronic non-communicable diseases.

The independent association of air pollutants with surrogate markers of endothelial dysfunction and a possible pro-coagulant state is underscored. Similar independent associations are documented for air pollutants and hematologic parameters as well as a possible pro-inflammatory state. The presence of these associations with PM₁₀ (larger than PM₂.₅ usually considered as harmful) and in a moderate air quality (which is commonly considered with few or no health effect for the general population) highlights the need to re-examine environmental health policies and standards for the pediatric age group.

Atherosclerosis begins in early life, and the role of platelets is well-documented from its early stages. The concern of medical literature on atherosclerotic cardiovascular diseases is mostly about some specific inflammatory diseases, and the role of environmental factors, as air pollution is overlooked in many studies. Many studies have documented that disturbance of the inflammatory and the coagulation systems after exposure to air pollution might be a factor in endothelial dysfunction and the progression of cardiovascular diseases.

The increase in platelets number and aggregation may be a surrogate marker of early hematologic and hemostatic changes due to air pollutants. The systemic pro-inflammatory and pro-coagulant response to inhalation of fine and ultrafine particulate matters suggest a role for platelet activation in this process.

Facilities should be provided for families to become aware of the quality of the air year-round and to check daily air-quality levels and air-pollution forecasts by mass media, local weather reports and other available public information sources. This is especially important for smog levels during hot weather. Protective measures should be taken into account for children and pregnant women to reduce their exposure to air pollutants, e.g. children and pregnant women should avoid congested streets and rush hour traffic, moreover families...
should try to limit the amount of time their child spends outdoors in vigorous activity if the
air quality is unhealthy.
In view of the emerging epidemic of chronic disease in low- and middle-income countries,
the vicious cycle of rapid urbanization in such communities resulting in increasing levels of
air pollution and its consequent effects on chronic diseases, as well as the limited financial
resources of these countries for planning effective air pollution control programs, public
health and regulatory policies for air quality protection should be integrated into the main
priorities of primary health care system and into the educational curriculum of health
professionals.

2. Health hazards of air pollution
Air pollutants have many adverse effects on various body organs with short- and long-term
health consequences. A summary of the health hazards of air pollution is presented in Table 1.

3. Susceptibility of children health to air pollutants
Infants and children are among the most susceptible age groups for air pollutants, because
they may have greater exposure than adults to air pollutants, this is especially important
during summer time with highest smog levels; they have higher respiratory rates than
adults, and consequently higher exposure to air pollutants. The mouth breathing of infants
and children bypass the filtering effect of the nose, and they would inhale higher levels of
pollutants than adults. Children generally spend significantly more time outdoors than
adults, In addition, the children’s immune systems and developing organs are still
immature (Kim, 2004).

4. Long-term effects of air pollutants on children’s health
Air pollutants have various adverse effects from early life, some of the most important
harmful effects are perinatal disorders, infant mortality, respiratory disorders, allergy,
malignancies, cardiovascular disorders, increase in stress oxidative, endothelial dysfunction,
mental disorders and vitamin D deficiency. However, till now most focus has been on the
short-term respiratory effects of air pollution on children’s health. In this chapter, we
highlight the wide range of hazards of air pollution from early life, and their possible
implication on chronic non-communicable diseases of adulthood.
The late-onset effects of air pollution in early life may be related to many chronic diseases
later in life. Most chronic non-communicable diseases originate from early life, however
studies about the relationship of environmental factors, notably air pollution, with risk
factors of chronic diseases are scarce in children and adolescents.

5. Exposure to air pollutants in early life and chronic diseases in adulthood
Many studies have documented the effects of criteria air pollutants on low birth weight and
or prematurity .There is a growing body of evidence about the association of intrauterine
growth retardation and low birth weight with increased risk of chronic non-communicable
diseases such as obesity, hypertension and cardiovascular disease later in life (Sinclair et al.,
2007). Furthermore, prematurity can be associated with higher risk of chronic diseases
(Evensen et al., 2008).

The relationship of long-term traffic exposure (NO2 level by residence) and diabetes mellitus is documented (Brook et al., 2008). The first biological support for this finding comes from our study that demonstrated an independent association of exposure to air pollutants, notably PM10, with markers of insulin resistance among children and adolescents (Kelishadi et al., 2009), as cited in the statement of the American Heart Association (Brook et al., 2010).

These findings suggest that the systemic responses to long-term exposure to air pollutants could potentially increase the risk for development of the metabolic syndrome, hypertension and diabetes mellitus. Some study findings on the association of air pollution with surrogate markers of atherosclerotic cardiovascular diseases in children and adolescents is presented in Table 2.

6. Environmental factors, lifestyle behaviors and chronic diseases

Usually improper lifestyle habits and low educational levels have been considered as the underlying process of the role of low socio-economic position in early life as a predisposing factor for future chronic diseases (Power, et al., 2007) and mortality (Strand & Kunst, 2007), the exposure to air pollutants and its effects on low birth weight and premature birth might have an additional role in this regard.

Lifestyle modifications and strengthening primary care in health system are suggested as the main strategies to prevent and control chronic diseases in low- and middle-income countries (Miranda et al., 2008).

The association between air pollution and chronic diseases may be mediated through systemic inflammatory responses (Brook et al., 2004; Holgate et al. 2003).
reactive oxygen species is considered to be linked to a variety of environmental factors. The association of air pollution and inflammation/oxidative stress has been demonstrated (Huang et al., 2003; Ruckerl et al. 2006; Chuang et al., 2007), even among healthy children (Kelishadi et al., 2009) who might have the early stages of atherosclerosis. Such association is also confirmed for air pollutants, notably particulate matters and surrogate markers of endothelial dysfunction and markers of vascular injury (Poursafa et al., 2011). The effects of air pollution on inflammation, coagulation, oxidative stress and endothelial dysfunction from early life confirm the necessity of implications of these findings in relation to public health and regulatory policies for primordial/primary prevention and control of adult chronic diseases from childhood.

The prevalence of malignancies are rapidly accelerating worldwide. Although lifestyle behaviors as smoking (Dominguez et al., 2006), as well as unhealthy dietary and physical activity habits leading to obesity and diabetes are known as a major contributing factor in this regard (Hjartåker et al.,2008), air pollution should be considered as another potential risk factor for developing countries(Nejjari et al.,2003) especially Asian countries, where cancer has become an emerging health threat (Park et al.,2008). This issue is particularly important for children who are susceptible to short-term and long-term effects of air pollutants.

7. Conclusion

Air pollution is a global health issue with serious public health implications particularly for children. Usually respiratory effects of air pollutants are being considered, the importance of other health hazards should be highlighted. In addition to short-term effects, exposure to criteria air pollutants from early life might have long-term hazards principally on chronic non-communicable diseases as cardiovascular diseases and cancers. In view of the emerging epidemic of chronic disease in low- and middle-income countries, the vicious cycle of rapid urbanization in such communities resulting in increasing levels of air pollution and its consequent effects on chronic diseases, as well as the limited financial resources of these countries for planning effective air pollution control programs, public health and regulatory policies for air quality protection should be integrated into the main priorities of primary health care system and into the educational curriculum of health professionals.

We suggest that environmental protection activities, particularly for reducing the emission of criteria air pollutants, should be considered for public health measures taken into account for primordial/primary prevention of chronic diseases especially in developing countries.

8. References

www.intechopen.com

Today, an important issue is environmental pollution, especially air pollution. Due to pollutants present in air, human health as well as animal health and vegetation may suffer. The book can be divided in two parts. The first half presents how the environmental modifications induced by air pollution can have an impact on human health by inducing modifications in different organs and systems and leading to human pathology. This part also presents how environmental modifications induced by air pollution can influence human health during pregnancy. The second half of the book presents the influence of environmental pollution on animal health and vegetation and how this impact can be assessed (the use of the micronucleus tests on TRADESCANTIA to evaluate the genotoxic effects of air pollution, the use of transplanted lichen PSEUDEVERNIA FURFURACEA for biomonitoring the presence of heavy metals, the monitoring of epiphytic lichen biodiversity to detect environmental quality and air pollution, etc). The book is recommended to professionals interested in health and environmental issues.
