1. Introduction

Moldy feed toxicosis was recognized as a serious livestock problem in the 1950's but it was only in 1960 during the investigations in the United Kingdom of moldy feed toxicosis which was called Turkey "x" disease, that A. flavus and A. parasiticus were identified as the organisms responsible for the elaboration of the toxin in the feed. The earliest symptoms of the disease are lithargy and muscular weakness followed by death. The term aflatoxin now refers to the group of bisfuranocoumarin metabolites isolated from strains of A. flavus group of fungi. The toxic material derived from the fungus A. flavus was given the name "aflatoxin" in 1962 (Sargeant et al., 1963).

Aflatoxins fluoresce strongly in ultra violet light. The major members are designated as B1, B2, G1 and G2. B1 and B2 fluoresces blue, while G1 and G2 fluoresces green. In some animal species in dairy cattle, aflatoxin B1 and B2 are partially metabolized to the hydroxylated derivates namely M1 and M2, respectively.

Aflatoxin P1 is a urinary metabolite of B1 in monkeys. All aflatoxins absorb UV light in the range of 362-363nm, a characteristic used in preliminary identification. The growth of toxigenic molds and elaboration of the toxin occurs if moisture conditions are ideal following harvest and storage.

Although initially aflatoxin was detected in the peanut meal it is now known that a variety of cereals, and other plant products are susceptible to fungal invasion and mycotoxin production. The occurrence of aflatoxins in agricultural commodities depends on such factors as region, season and the conditions under which a particular crop is grown, harvested or stored.

Because of the wide spread nature of fungi producing aflatoxins in food materials, international agencies have now permitted the presence of 20 ppb of aflatoxin in food materials as the maximum permissible level. In 1993 aflatoxin by the World Health Organization (WHO) for cancer research institutions designated as a Class 1 carcinogen, is a highly poisonous toxic substances. Aflatoxin is harmful to human and animal liver tissue.
has damaging effects, serious, can lead to liver cancer or even death. In the natural food contaminated with aflatoxin B1 is most common, is also its most toxic and carcinogenic.

2. Occurrence of aflatoxin in food and feed

Aflatoxin found in soil, plants and animals, all kinds of nuts, especially peanuts and walnuts. In soybean, rice (Fouzia Begum & Samajpati, 2000), corn, pasta, condiments, milk, dairy products, edible oil products are also often found aflatoxin. Aflatoxins often occur in crops in the field prior to harvest. Post harvest contamination can occur if crop drying is delayed and during storage of the crop if water is allowed to exceed critical values for the mould growth. Insect or rodent infestations facilitate mould invasion of some stored commodities. Aflatoxins are found occasionally in milk, cheese, peanuts, cottonseed (Fig. 1), nuts, almonds, figs, spices, and a variety of other foods and feeds. Milk, eggs, and meat products are sometimes contaminated because of the animal consumption of aflatoxin contaminated feed. Cottonseed, Brazil nuts, copra, various tree nuts and pistachio nuts are the other commodities quite susceptible to the invasion of aflatoxin producing fungi.

Fig. 1. Contamination of cotton seeds

2.1 Types of aflatoxins

Although 17 aflatoxins have been isolated (WHO, 1979), only 4 of them are well known and studied extensively from toxicological point of view. Being intensely fluorescent in ultraviolet light the four are designated by letters B1, B2, G1 and G2 representing their blue and green fluorescence in UV light. Two other familiar aflatoxins are M1 and M2. Because of their presence in milk of animals previously exposed to B1 and B2. Of all the above-named aflatoxins, aflatoxin B1 (AFB1) is the most acutely toxic to various species. Toxigenic A. flavus isolates generally produce only aflatoxins B1 and B2, whereas A. parasiticus isolates generally produce aflatoxins B1, B2, G1 and G2 (Davis and Diener, 1983). Other metabolites B2α, aflatoxicol, aflatoxicol H1 and aflatoxins P1 and Q1 have been identified (FDA, 1979). Aflatoxin M1 is a metabolite of aflatoxin B1 in humans and animals. Aflatoxin M2 is a metabolite of aflatoxin B1 in milk of cattle fed on contaminated foods. Although aflatoxins B1, B2 and G1 are common in the same food sample, AFB1 predominates (60-80% of the total aflatoxin content). Generally AFB2, AFG1 and AFG2 do not occur in the absence of AFB1. In most cases AFG1 is found in higher concentrations than AFB2 and AFG2 (Weidenborner, 2001).
2.2 Favorable conditions for aflatoxin biosynthesis production

The formation of aflatoxins is influenced by physical, chemical and biological factors. The physical factors include temperature and moisture. The chemical factors include the composition of the air and the nature of the substrate. Biological factors are those associated with the host species (Hesseltine, 1983).

Specific nutrients, such as minerals (especially zinc), vitamins, fatty acids, amino acids and energy source (preferably in the form of starch) are required for aflatoxins formation (Wyatt, 1991). Large yield of aflatoxins are associated with high carbohydrate concentrations, such as wheat rice and to a lesser extent in oilseeds such as cottonseed, soybean and peanuts (Diener and Davis, 1968).

The limiting temperatures for the production of aflatoxins by *A. flavus* and *A. parasiticus* are reported as 12 to 41°C, with optimum production occurring between 25 and 32°C (Lillehoj, 1983). Synthesis of aflatoxins in feeds are increased at temperatures above 27°C (80 F), humidity levels greater than 62% and moisture levels in the feed above 14% (Royes and Yanong, 2002).

2.3 Causes of aflatoxin

Crops grown under warm and moist weather in tropical or subtropical countries are especially more prone to aflatoxin contamination than those in temperate zones. Groundnuts and groundnut meal are by far the two agricultural commodities that seem to have the highest risk of aflatoxin contamination. Although these commodities are important as substrates, fungal growth and aflatoxin contamination are the consequence of interactions among the fungus, the host and the environment. The appropriate combination of these factors determines the infestation and colonization of the substrate and the type and amount of aflatoxin produced.

Water stress, high-temperature stress and insect damage of the host plant are major determining factors in mould infestation and toxin production. Similarly, specific crop growth stages, poor fertility, high crop densities and weed competition have been associated with increased mould growth and toxin production. The moisture content of the substrate and temperature are the main factors regulating the fungal growth and toxin formation. A moisture content of 18% for starchy cereal grains and 9-10% for oil-rich nuts and seeds has been established for maximum production of the toxin (WHO, 1979). On the other hand, the minimum, optimum and maximum temperatures for aflatoxin production have been reported to be 12°C - 27°C and 40°C-42°C respectively. Frequent contamination of corn and other commodities with high levels of aflatoxins has been a serious problem all over the world resulting in significant economic losses to farmers and a health hazard to farm animals and humans as well.

2.4 Structure of aflatoxin

In 1963, Asao et al.; Van Dorp et al. and Van der Zijden characterized the chemical and physical nature of the aflatoxins B1, B2, G1 and G2. Chemically, aflatoxins are difurocoumarolactones (difurocoumarin derivatives). Their structure consists of a bifuran ring fused to a coumarin nucleus with a pentenone ring (in B and M aflatoxins) or a six-membered lactone ring in G aflatoxins (Fig. 2). The four compounds are separated by the color of their fluorescence under long wave (Devero, 1999) ultraviolet illumination (B=blue,
G= green). Two other aflatoxins M\textsubscript{1} and M\textsubscript{2} were isolated from urine and milk and identified as mammalian metabolites of AFB\textsubscript{1} and AFB\textsubscript{2} (Patterson et al., 1978).

Fig. 2. Structure of aflatoxin

2.4.1 Physical properties

These four compounds were originally isolated by groups of investigators in England (Nesbitt et al., 1962, Sargeant et al., 1961). The molecular formula of aflatoxin B\textsubscript{1} was established as C\textsubscript{17}H\textsubscript{12}O\textsubscript{6} and of aflatoxin G\textsubscript{1} as C\textsubscript{17}H\textsubscript{12}O\textsubscript{7}; aflatoxins B\textsubscript{2} and G\textsubscript{2} were found to be the dihydro derivatives of the parent compounds, C\textsubscript{17}H\textsubscript{14}O\textsubscript{6} and C\textsubscript{17}H\textsubscript{14}O\textsubscript{7} (Hartley et al., 1963). Some physical properties of the compounds are summarized in following Table 1.

Table 1. Physical properties of aflatoxin

www.intechopen.com
The spectral characteristics of the aflatoxins have been determined by several investigators and are summarized in Table 2. The ultraviolet absorption spectra are very similar, each showing maxima at 223, 265 and 363 m\(\mu\). The molar extinction coefficients at the latter two peaks, however, demonstrate that B1 and G2 absorb more intensely than G1 and B2 at these two wavelengths. Because of the close similarities in structural configuration, the infrared absorption spectra of the four compounds are also very similar, as illustrated. The fluorescence emission maximum for B1 and B2 has been reported to be 425 m\(\mu\) and that for G1 and G2 is 450 m\(\mu\). The intensity of light emission, however, varies greatly among the four compounds, a property of significance in the estimation of concentrations of the compounds by fluorescence techniques.

Table 2. Spectral properties of aflatoxin

2.4.2 Chemical properties

The chemical reactivity and behavior of the aflatoxins has received relatively little systematic study beyond work associated with structure elucidation. However, it has been shown (Asao et al., 1963) that catalytic hydrogenation of aflatoxin B1 to completion results in the uptake of 3 moles of hydrogen with the production of the tetrahydrodeoxy derivative. Interruption of the hydrogenation procedure after the uptake of 1 mole of hydrogen results in the production of aflatoxin B2 in quantitative yield.

Aflatoxin B1 has also been reported to react additively with a hydroxyl group under the catalytic influence of a strong acid (Andrellos et al., 1964). Treatment with formic acid-thionyl chloride, acetic acid thionyl chloride or trifluoroacetic acid results in addition products of greatly altered chromatographic properties, but relatively unchanged fluorescence characteristics. Ozonolysis results in fragmentation of aflatoxin B1 and the products of this reaction include levulinic, succinic, malonic and glutaric acids (Van Drop et al., 1963). The presence of the lactone ring makes the compound labile to alkaline hydrolysis, and partial recyclization after acidification of the hydrolysis product has been reported (De Iongh et al., 1962).

Although few systematic studies have been carried out on the stability of the aflatoxins, the general experience would seem to indicate that some degradation takes place under several conditions. The compounds appear partially to decompose, for example, upon standing in methanolic solution, and this process is greatly accelerated in the presence of light or heat. Substantial degradation also occurs on chromatograms exposed to air and ultraviolet or visible light. These processes may give rise to some of the nonaflatoxin fluorescent compounds typically seen in chromatograms of culture extracts. The nature of the decomposition products is still unknown, and the chemical reactions involved in their formation remain to be established (Wogan et al., 1966).
2.5 Biological effects of the aflatoxins
The discovery of this group of compounds as contaminants of animal feeds and the potential public health hazards involved, have stimulated considerable research effort concerned with their effects in various biological assay systems. The toxic properties of the aflatoxins manifest themselves differently depending on the test system, dose and duration of exposure. Thus, they have been shown to be lethal to animals and animal cells in culture when administered acutely in sufficiently large doses and to cause histological changes in animals when smaller doses were administered subacutely. Chronic exposure for extended periods has resulted in tumor induction in several animal species (Wogan et al., 1966).

2.5.1 Aflatoxin and animal diseases
Aflatoxin poisoning (Aflatoxicosis) mainly on animal liver injury, the injured individual species of animals, age, gender and nutritional status vary. The aflatoxin can cause liver dysfunction, reduced milk production and egg production and to reduced immunity of animals. Susceptible to the infection of harmful microorganisms. In addition, long-term consumption of food containing low concentrations of aflatoxin in feed can also result in embryo toxicity. Usually young animals are more sensitive to aflatoxin. The clinical manifestations of aflatoxin are digestive disorders, reduced fertility, reduced feed efficiency and anemia. Aflatoxins not only the decline in milk production, but also the transformation of the milk containing aflatoxin M1 and M2. According to the U.S. agricultural economy scientists to statistics, the consumption of aflatoxin contaminated feed, make at least 10% of the U.S. livestock industry suffered economic losses.

2.5.2 Metabolism and mechanisms of action of aflatoxin B1
The absorption from the gastrointestinal tract should be complete since very small doses, even in the presence of food, can cause toxicity. After the absorption, highest concentration of the toxin is found in the liver (Mintzlaff et al., 1974). Once in liver, aflatoxin B1 is metabolized by microsomal enzymes to different metabolites through hydroxylation, hydration, demethylation and epoxidation (Fig. 3). Thus hydroxylation of AFB1 at C4 or C22 produces, AFM1 and AFQ1, respectively. Hydration of the C2 – C3 double bond results in the formation of AFB2a which is rapidly formed in certain avian species (Patterson and Roberts, 1970). AFP1 results from o-demethylation while the AFB1 – epoxide is formed by epoxidation at the 2,3 double bond. Aflatoxicol is the only metabolite of AFB1 produced by a soluble cytoplasmic reductase enzyme system.

The liver is the target organ for toxic effects of aflatoxin B1. As a result, metabolism of proteins, carbohydrates and lipids in liver is seriously impaired by AFB1. The toxin inhibits RNA polymerase and subsequent protein synthesis at a faster rate in ducks than in rats probably because of faster liver metabolism of AFB1 in ducks than in rats (Smith, 1965). In day-old chicks, AFB1 reduces the activity of liver UDP glucose-glycogen transglucosylase resulting in depletion of hepatic glycogen stores (Shankaran et al., 1970). On the other hand, there is lipid accumulation in the liver of chickens and ducklings exposed to aflatoxin (Carnaghan et al., 1966; Shank and Wogan, 1966). With regard to its toxic effects on liver microsomal enzymes, AFB1 is known to decrease microsomal glucose-6-phosphatase activity (Shankaran et al., 1970) whereas stimulation of microsomal enzyme activity by inducers seems to be unaffected by AFB1 (Kato et al., 1970). In fact, pretreatment with the toxin actually stimulates its own metabolism in the rat when this is assayed in vitro.
Aflatoxins and Aflatoxicosis in Human and Animals

227

(Schabort and Steyn, 1969). Since aflatoxin inhibits protein synthesis, it is conceivable why aflatoxin reduces resistance of poultry to infection with Pasteurella multocida, salmonella sp., Marek disease virus, Coccidia and Candida albicans (Smith et al., 1969; Hamilton and Harris, 1971). Another effect of aflatoxin is that it causes anticoagulation of blood. This is probably because AFB1 inhibits synthesis of factors II and VII involved in prothrombin synthesis and clotting mechanism (Bababunmi and Bassir, 1969).

Fig. 3. Metabolism of aflatoxin in liver

Aflatoxin molecules in the double-furan ring structure, the structure is an important toxicity. Studies show that aflatoxin cytotoxic effects of toxins, is an interference RNA and DNA synthesis of information, thereby interfere with cell protein synthesis, resulting in systemic damage to animals (Nibbelink, 1988). Huangguang Qi et al., (1993) research indicates that aflatoxin B1 to form with the tRNA adduct, aflatoxin-tRNA adduct can inhibit tRNA binding activity of some amino acids on protein synthesis in the essential amino acids such as lysine, leucine, arginine and glycine and tRNA binding, have different inhibitory effect, thereby interfering with the translation level of protein biosynthesis, affect cell metabolism.

Aflatoxin B1 is excreted in urine and feces, and also in milk of lactating animals either unchanged or as various metabolites (Nabney et al., 1967; Allcroft et al., 1968). Only one milk metabolite, namely AFM1, appears to be the major metabolite of AFB1 that has shown appreciable oral toxicity (Holzapfel et al., 1966). Its toxicity is considered to be nearly as potent as AFB1. Even so this metabolite may be detoxified by conjugation with taurocholic and glucuronic acids prior to excretion in the bile or brine (DeLongh et al., 1964; Bassir and Osiyemi, 1967). In this respect, two other metabolites of AFB1, namely, AFP1 and AFQ1 are similar in that they also undergo this type of detoxication (Dalezios et al., 1971; BuChi et al., 1973; Masri et al., 1974). Both of these metabolites are several-fold less toxic than AFB1. For example, toxicity tests showed that AFP1 causes some mortality in newborn mice at 150 mg/kg as compared to the LD50 of 9.5 mg/kg for AFB1 under comparable conditions.
2.6 Aflatoxin and human health

Human health hazards by aflatoxin were mainly due to people eating aflatoxin contaminated food. For the prevention of this pollution is very difficult, the reason is due to fungi in the food or food materials in the presence of a very common. The state health department has been heavily polluted enterprises to use against the grain for food production and supervision of enterprises to develop the implementation of the relevant standards. But with lower concentrations of aflatoxin food and food cannot be controlled. In developing countries, consumption of aflatoxin contaminated food and incidence of cancer was positively correlated. Asian and African research institutions, disease research showed that aflatoxin in food and liver cells cancer (Liver Cell Cancer, LCC) showed positive correlation. For a long time with low concentrations of aflatoxin consumption of food was the leading cause liver cancer, stomach cancer, colon cancer and other diseases. In 1988, International Agency for Research on Cancer (IARC) classified the aflatoxin B1 as a human carcinogen.

The median lethal dose of aflatoxin B1 0.36 mg / kg body weight is a special range of highly toxic poison (aflatoxin animal half of the lethal dose is found in the strongest carcinogens). Its carcinogenicity is 900 times more than dimethylnitrosamine induced liver cancer in the large capacity 75 times higher than the 3,4-benzopyrene, a large 4000-fold. It is mainly to induce liver cancer in animals, can also induce cancer, renal cancer, colorectal cancer and breast, ovary, small intestine and other sites of cancer.

2.7 Aflatoxicosis

The disease caused by the consumption of substances or foods contaminated with aflatoxin is called aflatoxicosis.

2.7.1 Aflatoxicosis in humans

2.7.2 Human exposure conditions

Two pathways of the dietary exposure have been identified:

a. Direct ingestion of aflatoxins (mainly B1) in contaminated foods of plant origin such as maize nuts and their products.

b. Ingestion of aflatoxins carried over from feed into milk and milk products including cheese and powdered milk, where they appear mainly as aflatoxin M1. In addition to the carryover into milk, residues of aflatoxins may be present in the tissues of animals that consume contaminated feed (WHO, 1979). Aflatoxin residues have been found in animal tissues, eggs and poultry following the experimental ingestion of aflatoxin-contaminated feed (Rodricks and stoloff, 1977). Contamination of milk, egg and meat can result from animal consumption of mycotoxin contaminated feed. Aflatoxins, ochratoxin and some trichothecences have been given considerable attention, because they are either carcinogenic or economic concern in animal health (CAST, 1989).

Aflatoxin M1 is believed to be associated with casein (protein) fraction of milk. Cream and butter contain lower concentration of M1 than the milk from which these products are made, while, cheese contains higher concentration of M1 about 3-5 times the M1 in the original milk (Kiemeier and Buchner, 1977; Stoloff, 1980; Brackett and Marth, 1982).

The expression of aflatoxin related diseases in humans may be influenced by factors such as age, sex, nutritional status, and concurrent exposure to other causative agents such as viral hepatitis (HBV) or parasite infestation.
2.8 Effect on human health
2.8.1 Acute toxicity
The disease was characterized by high fever, high colored urine, vomiting, and edema of feet, Jaundice, rapidly developing ascitis, portal hypertension and a high mortality rate. The disease was confirmed to the very poor, who were forced by economic circumstances to consume badly molded corn containing aflatoxins between 6.25 -15.6 ppm, an average daily intake per person of 2-6 mg of aflatoxins (Krishnamachari et al., 1975a and 1975b; Keeler and Tu, 1983).

2.8.2 Chronic toxicity
Long exposure to aflatoxins in the diet increases risk with a synergistic effect from increased alcohol consumption. Aflatoxin B1 has also been implicated as a cause of human hepatic cell carcinoma (HCC). Aflatoxin B1 also chemically binds to DNA and caused structural DNA alterations with the result of genomic mutation (Groopman et al, 1985). Ingestion of aflatoxin, viral diseases, and hereditary factors has been suggested as possible aetiological agents of childhood cirrhosis. There are evidences to indicate that children exposed to aflatoxin breast milk and dietary items such as unrefined groundnut oil, may develop cirrhosis. Malnourished children are also prone to childhood cirrhosis on consumption of contaminated food. Several investigators have suggested aflatoxin as an aetiological agent of Reye’s syndrome in children in Thailand, New Zealand etc. Though there is no conclusive evidence as yet. Epidemiological studies have shown the involvement of aflatoxins in Kwashiorkor mainly in malnourished children. The diagnostic features of Kwashiorkor are edema, damage to liver etc. These out breaks of aflatoxicosis in man have been attributed to ingestion of contaminated food such as maize, groundnut etc. Hence it is very important to reduce the dietary intake of aflatoxins.

2.9 Aflatoxicosis in animals
Aflatoxin can cause oncogenesis, chronic toxicity or peracute signs depending on the species, age of animal, dose and duration of aflatoxin exposure (Smith, 2002). All animal species are susceptible to aflatoxicosis, but outbreak occurs mostly in pigs, sheep and cattle (Radostits et al., 2000). Beef and dairy cattle are more susceptible to aflatoxicosis than sheep or horses. Young animals of all species are more susceptible than mature animals to the effects of aflatoxin. Pregnant and growing animals are less susceptible than young animals, but more susceptible than mature animals (Cassel et al., 1988). Nursing animals may be affected by exposure to aflatoxin metabolites secreted in the milk (Jones et al., 1994). For most species, oral LD50 values of aflatoxin B1 vary from 0.03 to 18 mg/kg body weight.

2.10 Effects on animal health
There are differences in species with respect to their susceptibility to aflatoxins, but in general, most animals, including humans, are affected in the same manner.

2.10.1 Acute toxicity
Acute toxicity is less likely than chronic toxicity. Studies have shown that ducklings are the species most susceptible to acute poisoning by aflatoxins. The LD50 of a day old duckling is 0.3mg/kg bodyweight.

The principal target organ for aflatoxins is the liver. After the invasion of aflatoxins into the liver, lipids infiltrate hepatocytes and leads to necrosis or liver cell death. The main reason for this is that aflatoxin metabolites react negatively with different cell proteins, which leads to inhibition of carbohydrate and lipid metabolism and protein synthesis. In correlation with the decrease in liver function, there is a derangement of the blood clotting mechanism, icterus (jaundice), and a decrease in essential serum proteins synthesized by the liver. Other general signs of aflatoxicosis are edema of the lower extremities, abdominal pain, and vomiting.

2.10.2 Chronic toxicity

Animals which consume sub-lethal quantities of aflatoxin for several days or weeks develop a sub acute toxicity syndrome which commonly includes moderate to severe liver damage. Even with low levels of aflatoxins in the diet, there will be a decrease in growth rate, lowered milk or egg production and immunosupression. There is some observed carcinogenicity, mainly related to aflatoxin B1. Liver damage is apparent due to the yellow color that is characteristic of jaundice, and the gall bladder will become swollen. Immunosupression is due to the reactivity of aflatoxins with T-cells, decrease in Vitamin K activities and a decrease in phagocytic activity in macrophages.

2.10.3 Cellular effects

Aflatoxins are inhibitors of nucleic acid synthesis because they have a high affinity for nucleic acids and polynucleotides. They attach to guanine residues and form nucleic acid adducts. Aflatoxins also have been shown to decrease protein synthesis, lipid metabolism, and mitochondrial respiration. They also cause an accumulation of lipids in the liver, causing a fatty liver. This is due to impaired transport of lipids out of the liver after they are synthesized. This leads to high fecal fat content. Carcinogenesis has been observed in rats, ducks, mice, trout, and subhuman primates and it is rarely seen in poultry or ruminants. Trout are the most susceptible. In fact, 1ppb of aflatoxin B1 will cause liver cancer in trout. Carcinogenesis occurs
due to the formation of 8,9-epoxide, which binds to DNA and alters gene expression. There is a correlation with the presence of aflatoxins and increased liver cancer in individuals that are hepatitis B carriers. Animals of different species vary in their susceptibility to acute aflatoxin poisoning with LD$_{50}$ values ranging from 0.3 to 17.9 mg/kg (Table 4). In fact duckling liver metabolized aflatoxin very rapidly in vitro (Patterson and Allcroft, 1970), although the species is sufficiently susceptible for day old birds to be used widely in a sensitive bioassay for the toxin (Patterson, 1973). Studies indicated that rabbit, duckling and guinea-pig constitute a "fast metabolizing group" being apparently capable of handling an LD$_{50}$ dose in under 12 minutes. Chick, mouse, pig and sheep fall into an intermediate group, metabolizing an LD$_{50}$ dose in a few hours. So far, the rat is the only example of a "slow metabolizing group" in which LD$_{50}$ dose would probably disappear from the liver over a period of days (Patterson, 1973).

Factors that influence aflatoxin toxicity residue levels in animal species include: species and breeds of animals and poultry, levels and duration of exposure, nutrition and health of animals, age, sex and diseases, drugs and other mycotoxins (FDA, 1979).

2.10.5 Calves

The LD₅₀ dosage of AFB₁ in calves has been estimated to be 0.5-1.5 mg/kg. Affected calves had anorexia, depression, jaundice, photosensitization of unpigmented skin, submandibular edema, severe keratocconjunctivitis and diarrhea with dysentery. Collapse and death followed. Postmortem findings showed hemorrhages in subcutaneous tissues, skeletal muscles, lymph nodes, pericardium, beneath the epicardium and serosa of the alimentary tract. The liver was pale and carcass jaundiced. Histopathological examination of the liver revealed that hepatocytes were markedly enlarged, especially in the periportal areas and occasional hepatocyte nuclei were up to 5 times the diameter of their companions. Hepatocyte cytoplasm was finely vacuolated, many of these vacuoles containing fat. Serum enzymes of hepatic origin and bilirubin were elevated.

In calves who have consumed contaminated rations for several weeks, the onset of clinical signs is rapid. The most consistent features are blindness, circling and falling down, with twitching of the ears and grinding of the teeth. Severe tenesmus and erosion of the rectum are seen in most cases, and death of some cases (Humphreys, 1988).

2.10.6 Dairy and beef cattle

The signs most commonly reported with acute toxicosis in cattle include anorexia, depression, dramatic drop in milk production, weight loss, lethargy, ascitis, icterus, tenesmus, abdominal pain (animals may stretch or kick at their abdomen), bloody diarrhea, abortion, hepatoencephalopathy, photosensitization and bleeding (Colvin et al., 1984; Cook et al., 1986; Ray et al., 1986; Eaton and Groopman, 1994; Reagor, 1996). Other signs associated with acute aflatoxicosis include blindness, walking in circles, ear twitching, frothy at the mouth, keratoconjunctivitis and rectal prolapse (Radostitis et al., 2000). Hepatic damage is a constant finding in acute aflatoxicosis. Lesions include fatty degeneration, megalocytosis and single-cell necrosis with increasing fibrosis, biliary proliferation and veno occlusive lesions as the disease progresses (Burnside et al., 1957; Morehouse, 1981; Colvin et al., 1984).

In additions, chronic aflatoxicosis may impair reproductive efficiency including abnormal estrous cycle (too short and too long) and abortions, induce immunosuppression and increase susceptibility to disease (Cassel et al., 1988). The immunotoxic effect of AFB₁ was expressed via the cell-mediated immune system (Raisbeck et al., 1991).

Other symptoms including decreased milk production, birth of smaller and healthy calves, diarrhea, acute mastitis, respiratory disorders, prolapsed rectum and hair loss are also observed in chronically exposed dairy cattle (Guthrie, 1979). High aflatoxin levels (4 ppm) can cause milk production to drop within one week while, lower levels (0.4 ppm) can cause production drop in 3 to 4 weeks (Hutjens, 1983).

Another character of aflatoxin exposure in dairy cattle is the conversion to AFM₁ in milk (Price et al., 1985). Experiments have shown that milk will be free of aflatoxin after 96 hours of feeding non-contaminated feed. The level of aflatoxin in the feed and milk at the stating point will influence clearance time (Lynch, 1972; Hutjens, 1983).

The concentration of AFM₁ in milk seems to depend more on intake of AFB₁ than on milk yield (Vander Linde et al., 1965). However, the toxin content of milk appears to increase rapidly when milk yield is reduced as a result of high toxin intake (Masri et al., 1969). Rate of metabolism by the liver and rate of excretion by other routes (urine and feces) are also likely to influence the toxin level in milk (Applebaum et al., 1982).
Decreased performance (i.e. rate of gain, milk production) is one of the most sensitive indicators of aflatoxicosis (Richard et al., 1983). The ultimate cause of this effect is probably multifactorial, involving not only nutritional interactions, but also the compounding influences of anorexia, deranged hepatic protein and lipid metabolism and disturbances in hormonal metabolism (Raisbeck et al., 1991). Aflatoxins have shown to affect rumen motility (Cook et al., 1986) and rumen function by decreasing cellulose digestion, volatile fatty acid production and proteolysis (Fehr and Delag, 1970; Bodine and Mertins, 1983).

2.10.7 Sheep and goats

Anorexia, depression and icterus were observed in sheep and goats exposed to aflatoxin. The goats also developed a nasal discharge and dark brown urine was noted in the sheep (Hatch et al., 1971; Samarajeewa, et al., 1975; Abdelsalam et al., 1989).

Anorexia and diarrhea occurred in sheep given aflatoxin at a rate of 0.23mg/kg. These signs were accompanied by excessive salivation, tachypnea and pyrexia at dosages of 0.59 mg/kg or more. Heavy mucous diarrhea and dysentery were observed in sheep dosed at a rate of 1.28 to 2.0mg/kg. Sheep that died within 24 hours of dosing had marked centrilobular necrosis of the liver. Sheep that survived until the 7th day after dosing had periportal congestion of the liver, widely dilated sinusoids and necrosis of liver cells (Armbrecht et al., 1970).

Acute intoxicated sheep with 4mg/kg showed anorexia, diarrhea, excessive salivation, rumen atony, scour, rectal prolapse, fever and death (Wylie and Morehouse, 1978).

2.10.8 AFB1 toxicity in equine species

The existing information on aflatoxicosis in the horse is inconclusive, although a total dietary concentration of 500–1000 µg/kg has been shown to induce clinical changes and liver damage, depending on the duration of exposure (Meerdink, 2002). The target organ in horses, as in all affected animals, is the liver, where the toxin induces centrilobular necrosis (Stoloff and Trucksses, 1979). Horses suffering from aflatoxicosis exhibit non-specific clinical signs, such as inappetence, depression, fever, tremor, ataxia and cough (Larsson et al., 2003). Necropsy findings include yellow–brown liver with centrilobular necrosis, icterus, haemorrhage, tracheal exudates and brown urine (Angsubhakorn et al., 1981; Cysewski et al., 1982; Bortell et al., 1983; Vesonder et al., 1991).

Clinical signs of toxicity were observed in adult male Shetland ponies given a daily oral dose of 0.075 (over 36 or 39 days), 0.15 (over 25 or 32 days) and 0.3 mg/kg (over 12 or 16 days) of partially purified aflatoxin (47% AFB1 activity) (Cysewski et al., 1982). Daily clinical observations revealed the appearance of depression, inappetence and weakness 5–7 days before the onset of severe illness and death. The onset of signs was generally dose related and appeared first in the ponies given 0.3mg/kg. Prothrombin time, sulfabromophtalein clearance time, total plasma bilirubin and the icteric index increased markedly before death. An increase in the plasma activity of aspartate amino transferase (AST) was observed. The AST activity grew significantly and generally remained at elevated levels in all animals. At the time of necropsy, pathological changes, such as generalised icterus, haemorrhage, a brown to tan liver, dark reddish brown urine and dark brown kidneys, were consistently observed. Microscopic lesions, including centrilobular fatty change, hepatic cell necrosis and periportal fibrosis, were observed in all ponies (Cysewski et al., 1982).
2.10.9 Aflatoxicosis in equine species: Case reports

The first case of probable equine aflatoxicosis in which a 15-year-old Arabian stallion died, was reported by Greene and Oehme (1976). The reported symptoms included anorexia, icterus and rapid weight loss immediately prior to death. On post mortem examination, the liver was described as being black, of firm consistency and enlarged. Histopathological examination revealed marked centrilobular hepatic necrosis and necrotic areas were engorged with erythrocytes. Kupffer cells were prominent and many contained phagocytosed haemosiderin, which was the likely cause of the black coloured liver. Bile-duct hyperplasia, congestion of renal vessels and adrenal cortex were found. Samples of the feed revealed AFB1 levels of 58.4 µg/kg, which exceeded the limit recommended by the FDA of 20 µg/kg (Greene and Oehme, 1976).

Two outbreaks of aflatoxicosis in two separate horse farms in different geographical areas of the world were later reported by Angsubhakorn et al. (1981). The first episode occurred in a horse breeding farm outside Bangkok, Thailand and started a few days after the introduction of a new lot of feed prepared from stored ground corn and stored peanut meal. A number of young animals had clinical signs of illness and 12 yearling colts died. At post mortem examination, a swollen fatty liver, pale swollen kidneys and hemorrhagic enteritis were found. A few animals necropsied soon after death, had pale hearts, focal myocardial necrosis and epicardial petechiae. When the cranial cavity was opened, the brain was seen to be swollen and the gyri compressed.

The second episode occurred in a farm for riding mares in southern Georgia, USA, in the autumn of 1978. After the introduction of a new mixed ration, a number of horses reduced their feed intake over a period of 3–4 days and showed signs of clinical illness. Within 5 days of the onset of clinical signs, two 2 year old horses and one 7 year old mare died. Necropsy findings were similar to those observed in the episode in Thailand. The swollen, fatty liver, epicardial petechiae; pale, mottled myocardium; swollen kidneys (although the paleness was more pronounced in the Georgia horses), haemorrhagic enteritis and variable mesenteric oedema.

Hematological and serum chemical examinations revealed hypoglycaemia, hyperlipidaemia and depletion of lymphocytes. The increase in haematocrit and the number of red blood cells was probably due in part to dehydration. The diagnosis of aflatoxicosis in these two episodes was based on histological examinations and isolation of the toxin from the feed and animal tissues. Microscopically, the lesions of the Georgia horses appeared the same as those seen in the Thai horses. Assay of liver specimens from two of the Georgia horses confirmed the presence of AFB1 in both samples and the results showed that AFB1 was metabolized and rapidly cleared from the liver and other tissues.

Peanut meal and corn were found to be the sources of aflatoxins in Thailand where representative samples of the mixed ration contained approximately 0.2 mg of AFB1 and 0.2 mg of AFB2 per kg (Caloni and Cortinovis, 2011).

2.10.10 Aflatoxins and COPD

Larsson et al. (2003) suggested a possible link between chronic obstructive pulmonary disease (COPD) and inhaled mycotoxins. *A. fumigatus* and *Mycropolyspora faeni* are potential causes of COPD in horses (Halliwell et al., 1995), which is characterised by asthma like symptoms, such as chronic cough, nasal discharge, inspiratory dyspnoea and reduced exercise tolerance (Gillespie and Tyler, 1969; Cook, 1976). The olfactory and respiratory mucosa of horses may be exposed to mycotoxins and other xenobiotics via inhalation of
contaminated feed-dust particles (Sorensson et al., 1981; Burg and Shotwell, 1984). The inhaled aflatoxins and other xenobiotics may be activated by CYP-enzymes in the epithelial linings of the respiratory tract and contribute to the aetiology of COPD (Larsson et al., 2003; Tydèn et al., 2008).

2.10.11 Canine

Canine aflatoxicosis was first reported in 1952 by Seibold and Bailey who described a liver disease called hepatitis “x” which was observed in dogs fed moldy contaminated feed. Dogs and cats are extremely sensitive to aflatoxins. The LD$_{50}$ of AFB1 in dogs is 0.5-1.5 mg/kg and in cats is 0.3-0.6 mg/kg (Rumbeiha, 2001). Feed containing AFB1 concentrations of 60 ppb or greater have caused outbreaks of aflatoxicosis in companion animals. As with other toxic compounds, sensitivity depends on individual susceptibility which in turn depends on age, hormonal status (pregnancy), nutritional status, among other factors (Rumbeiha, 2001).

Dogs exposed to aflatoxin developed the typical anorexia, depression, prostration and blood in the feces, but also may have hemorrhages, melena and pulmonary edema (FDA, 1979; Liggett et al., 1986; Bastianello et al., 1987; Thornburg and Raisbeck, 1988). Moreover, vomiting, increased water consumption, polyuria, polydipsia, jaundice and elevation of serum liver enzymes in acute aflatoxicosis in dogs and cats (Rumbeiha, 2001).

At necropsy, the liver is swollen, petechial hemorrhages are observed on the gums, along the gastrointestinal tract, in the lungs, pleura, epicardium and urinary bladder. The hemorrhages are associated with a yellow, reddish-yellow, or orange discoloration of the liver, icterus of the conjunctiva, oral mucosa, serous membranes and in body fat (Chaffee et al., 1969; FDA, 1979; Rumbeiha, 2001). Lymphoid depletion and necrosis of the thymus, spleen and lymph nodes, gross uterine and placental hemorrhage and congestion and hemorrhage in the adrenal cortex were also reported (Newberne et al., 1966).

In subacute aflatoxicosis, affected dogs and cats will present with lethargy, anorexia, polyuria, polydipsia, elevated liver enzymes and jaundice. In chronic aflatoxicosis, dogs and cats will have clinical signs similar to subacute aflatoxicosis, with prominent jaundice. Chronic aflatoxicosis may cause also immunosuppression, followed by non-specific clinical signs, including increased susceptibility to viral, bacterial, fungal or parasitic infections (Rumbeiha, 2001).

Histologically, there is severe fatty degeneration with distinct vacuolation of hepatocytes, bile canaliculi are distended with bile, portal and central veins are congested with bile, and portal and central veins are congested in acute cases. In subacute cases, the distinct feature is bile duct proliferation and there is evidence of liver regeneration. In chronic cases, there is extensive liver fibrosis and bile duct proliferation (Rumbeiha, 2001).

2.10.12 Pigs

Young swine are extremely sensitive to aflatoxins but susceptibility decreased with age (Diekman et al., 1992). The toxicity of aflatoxin is both-dose related and time related and age is an important factor in susceptibility (Lawlor and Lynch, 2001). Sows and boars normally tolerate levels > 0.5 ppm in the feed for short periods but, when fed for extended periods, contamination levels in the feed should not exceed 0.1 ppm (Blaney and Williams, 1991). Levels in excess of 0.5 ppm in the diets of lactating sows will depress growth rates in suckling pigs due to aflatoxin in milk. For growing and finishing pigs residues will build up in the liver at concentrations of even less than 0.1 ppm in the feed (Osweller, 1992). The LD$_{50}$ in young pigs dosage was determined to be 0.8 mg/kg (Jones and Jones, 1978). The clinical
syndrome in pigs include rough coat, depression, anorexia, decreased feed conversion, decreased rate of gain, weight loss, muscular weakness and shivering, tremors, bloody rectal discharge and icterus (Sisk et al., 1968; Jones and Jones, 1978; Hoerr and D’Andrea, 1983; Radostits et al., 2000). Aflatoxins also suppress the immune system and thus make pigs more susceptible to bacterial viral or parasitic diseases (Diekman et al., 1992). At necropsy, the livers from swine receiving toxic levels of AFB1 in their ration vary in close from tan to pale yellow with atrophic gall bladders, the livers contain increased fibrous connective tissue with resistance to cutting. There is icterus and petechial hemorrhages on the heart and massive hemorrhage into the ileum or throughout the digestive tract. Microscopic lesions include irregular shaped cells, centrilobular congestion, karyorrhexis and pyknosis, vacuolation, disappearance of nuclei, bile duct proliferation and extensive connective tissue in the inter and intralobular areas (FDA, 1979).

2.11 Aflatoxicosis in poultry
Aflatoxicosis have produced severe economic losses in the poultry industry affecting ducklings, broilers, layers, turkeys and quail (CAST, 1989). Susceptibility of poultry to aflatoxins varies among species, breeds and genetic lines. Comparative toxicological studies in avian species have shown that ducklings and turkey poultry are the most sensitive species to aflatoxins. Goslings, quails and pheasants show intermediate sensitivity while chickens appear to be the most resistant (Leeson et al., 1995). The susceptibility ranges from ducklings > turkey poult > goslings > pheasant chicks > chickens (Muller et al., 1970). Ducklings are 5 to 15 times more sensitive to the effects of aflatoxins than are laying hens, but when laying hen strains are compared, certain strains of hens may be as much as 3 times more sensitive than other strains (Jones et al., 1994). In comparing sensitivity of different strains of leghorn chicks (Table 5), it was found there is up to a 2.5 difference in the LD50 dose at 6 weeks of age (FDA, 1979).

Table 5. Sensitivity in different leghorn strains of chicks

In poultry, aflatoxin impairs all important production parameters including weight gain, feed intake, feed conversion efficiency, pigmentation, processing yield, egg production, male and female reproductive performance. Some influences are direct effects of intoxication, while others are indirect, such as from reduced feed intake (Calnek et al., 1997). The direct and indirect effects of aflatoxicosis include increased mortality from heat stress (broiler breeders, Dafalla et al., 1987a), decreased egg production in leghorns, (Bryden et al., 1980), anemia, hemorrhages and liver condemnations (Lamont, 1979), paralysis and lameness (Okoye et al., 1988), impaired performance in broilers, (Jones et al., 1982), increased mortality rate in ducks, (Bryden et al., 1980), impaired ambulation and paralysis in quail, (Wilson et al., 1975), impaired immunization in turkeys, (Hegazy et al., 1991), and increased susceptibility to infectious diseases (Bryden et al., 1980 and Calnek et al., 1997).
2.11.1 Chickens

Susceptibility of chickens to toxic effects of AFB1 varies with several factors such as breed, strain, age, nutritional status, amount of toxin intake and also the capacity of liver microsomal enzymes to detoxify AFB1 (Edds, 1973; Veltmann, 1984). Acute toxicity of aflatoxins in chickens may be characterized by hemorrhage in many tissues and liver necrosis with icterus.

Although number of field cases of aflatoxicosis in chickens has been diagnosed in various countries, the most severe spontaneous outbreak occurred in North Carolina, in which 50% of a flock of laying hens died within 48 hr of being fed highly toxic maize containing 100 ppm aflatoxin (Hamilton, 1971). The necropsy revealed that liver damage was the most important lesion showing paleness, occasional white pinhead-sized foci and petechial hemorrhages while gallbladder and bile ducts were distended.

Levels of aflatoxin B1 in moldy feed normally vary from 0 to 10 ppm. At low levels of feed contamination, exposed chickens show, in general, weakness, failure to gain weight with concomitant decline in feed efficiency and egg production (Smith and Hamilton, 1970; Doerr et al., 1983). Hepatic damage is manifested by enlarged and putty-colored liver, petechial hemorrhages, marked vacuolation of hepatic cells and bile duct proliferation. Feed levels of AFB1 as low as 250-500 ppb given to New Hampshire chickens have been reported to result in liver damage, decreased hemoglobin, and hypoproteinemia (Brown and Abrams, 1965). Experimental trials with naturally contaminated feed containing aflatoxin levels ranging from 1-1.5 ppm have caused growth retardation in chickens. Mortality was low but marked hepatic damage was manifested by enlarged and hemorrhagic liver (Carnaghan et al., 1966). Relatively, high dietary levels of aflatoxin B1 (0-10 ppm) given to Rock type broiler chickens have been reported to cause substantial decrease in weight gain, feed efficiency and hepatic microsomal drug metabolizing enzymes with concomitant increase in serum glutamic oxalacetic transaminase activity reflecting liver damage (Dalvi and McGowan, 1984; Dalvi and Ademoyero, 1984).

Metabolic alterations caused by aflatoxins in chickens result in elevated lipid levels (Tung et al., 1972; Donaldson et al., 1972), disruptions in hepatic protein synthesis (Tung et al., 1975) which result in several blood coagulation disorders (Doerr et al., 1976; Bababunmi and Bassir, 1982), immunosuppression and decreased plasma amino acid concentrations (Voight et al., 1980).

2.11.2 Ducks

Lethal aflatoxicosis in ducklings occurred as inappetance, reduced growth, abnormal vocalizations, feather picking, purple discoloration of legs and feet and lameness. Ataxia, convulsions and opisthotonos preceded death (Asplin and Carnaghan, 1961). At necropsy, livers and kidneys were enlarged and pale. With chronicity, ascitis and hydropneumocardium developed accompanied by shrunken firm nodular liver, distention of the gall bladder and hemorrhages (Asplin and Carnaghan, 1961; Calnek et al., 1997), distended abdomen due to liver tumors and secondary ascitis (Hetzel et al., 1984).

Microscopic lesions in the liver were fatty change in hepatocytes, proliferation of bile ductules and extensive fibrosis accompanied by vascular and degenerative lesions in pancreas and kidney (Asplin and Carnaghan, 1961 and Calnek et al., 1997). Bile duct hyperplasia and bile duct carcinoma are also reported (Hetzel et al., 1984) in aflatoxicated Campbell ducks.
2.11.3 Turkeys
The initial clinical signs reported during the outbreak of Turkey “x” disease were anorexia and weight loss followed by depression, ataxia and recumbency. Affected birds died within a week or two and at the time of death frequency had opisthotonos characterized by arched neck, head down back and legs extended backwards (Hamilton et al., 1972).
Along with decreased feed conversion and weight gain, reduced spontaneous activity, unsteady gait, recumbency, anemia and death (Siller and Ostler, 1961; Wannop, 1961; Giambrone et al., 1985; Richard et al., 1987).
At necropsy, the body condition was generally good but there was generalized congestion and edema. The liver and kidney were congested and firm, the gall bladder was full, and the duodenum was distended with catarrhal content (Siller and Ostler, 1961; Wannop, 1961; Calnek et al., 1997).

2.11.4 Broilers
Decreased water and feed intake, weight loss, dullness, stunting, ruffled feathers, poor appearance and paleness, trembling, ataxia, lameness, paralysis of the legs and wings gasping, prostration and death are frequency seen in experimental and natural outbreak of aflatoxicosis in broilers (Asuzu and Shetty, 1986; Okoye et al., 1988; Rao and Joshi, 1993; Leeson et al., 1995).
The most characteristic gross lesions appeared in the livers which were enlarged, pale yellow to grayish brown and had a prominent reticular pattern. Petechial hemorrhages were observed on the surface of some livers. Gall bladders were enlarged and bile duct distended and there were blood in the intestinal lumen (Archibald et al., 1962; Asuzu and Shetty, 1986). The liver, spleen and kidney were increased in size, whereas the bursa of fabricius and thymus were decreased (Smith and Hamilton, 1970; Huff and Doerr, 1980).
Lethal aflatoxicosis can cause either dark red or yellow discoloration of the liver due to congestion or fat accumulation, respectively (Slowik et al., 1985). At chronicity livers became shrunken, firm and nodular and gall bladder was distended (Asplin and Carnaghan, 1961). The kidneys of affected birds appeared enlarged and congested (Tung et al., 1973) and the spleen will be enlarged and mottled in appearance (Tung et al., 1975 a).
Histopathology of the liver revealed congestion of hepatic sinusoids, fecal hemorrhages, centro-lobular fatty cytoplasmic vacuolation and necrosis, biliary hyperplasia and nodular lymphoid infiltration. In the kidney, the epithelial cells of many tubules were vacuolated (Dafalla et al., 1987 b). Asuzu and Shetty (1986) and Okoye et al., (1988) observed severe degeneration of hepatocytes, dilation of central veins, bile duct proliferation and lymphocytic depletion in lymphoid organs in field outbreaks of aflatoxicosis in broilers.

2.11.5 Laying hens
Reduced egg production and egg weight, enlarged liver and increased liver fat are the most prominent manifestations of experimental aflatoxicosis in layers (Nesheim and Lvy, 1971; Hamilton and Garlich, 1973; Leeson et al., 1995). High mortality and dramatic reduction of egg production were reported to occur during a natural outbreak (Hamilton, 1971). Egg size, egg weight and yolk as percent of total egg size are decreased (Huff et al., 1975). In Japanese quail, decreased feed conversion, egg production, egg weight, hatchability and exterior and interior egg quality were detected (Sawhney et al., 1973a & b). Dhanasekaran et al., (2009) reported that histopathological analysis of aflatoxin ingested hens reveals that lesions were
observed in tissues of liver, kidney, intestine (Plate 1). Jayabharathi and Mohamudha parveen (2010) tested the aflatoxicosis in hens. Haematological analysis showed the decreased haemoglobin than the control group (Plate 2).

2.12 Reproduction and hatchability

Aflatoxins cause delayed maturation of both males and females (Doerr, 1979; Doerr and Ottinger, 1980). Aflatoxicosis in white leghorn males resulted in decreased feed consumption, body weight, testes weight and semen volume (Sharlin et al., 1980), and decreased plasma testosterone values (Sharlin et al., 1980). While in broiler breeder males reduction in body weight and mild anemia with no alterations in semen characteristics were observed (Wyatt, 1991; Briggs et al., 1974).

In mature laying hens experiencing aflatoxicosis, enlarged and fatty liver and marked decrease in egg production were observed (Hamilton and Garlich, 1972). Severe decline in hatchability was recorded in mature broiler breeder hens after consumption of aflatoxin (Howarth and Wyatt, 1976). Hatchability declines before egg production and is the most sensitive parameter of aflatoxicosis in broiler breeder hens (Howarth and Wyatt, 1976). The immediate and severe decline in hatchability was found to arise from an increase in early embryonic mortality rather than infertility of the hens. The cause of the increased embryonic mortality is the transfer of toxic metabolites from the diet of the hen to the egg (Wyatt, 1991). The delayed response in egg production is thought to occur due to reducing synthesis and transport of yolk precursors in the liver (Huff et al., 1975).

2.13 Immunosuppression

Aflatoxin induces immunosuppression and increases susceptibility of intoxicated birds to bacterial, viral and parasitic infections. Immunosuppression caused by AFB1 has been demonstrated in chickens and turkeys as well as laboratory animals (Sharma, 1993). Aflatoxin decreases the concentrations of immunoglobulins IgM, IgG and IgA in birds (Giambrone et al., 1978a & b). The presence of low levels of AFB1 in the feed appears to decrease vaccinal immunity and may therefore lead to the occurrence of disease even in properly vaccinated flocks (Leeson et al., 1995).

Thaxton et al., (1974) recorded reduced antibody production following injection of sheep red blood cells in chickens experiencing aflatoxicosis. Batra et al., (1991) found that chickens fed AFB1 and vaccinated against Marek’s disease showed a significantly higher frequency of gross and microscopical lesions of Marek’s disease than did chickens fed aflatoxin-free diet. Cell-mediated immune response and effector cell function are also affected during aflatoxicosis (Leeson et al., 1995). Aflatoxin decrease complement activity in chickens (Campbell et al., 1983 and Stewart et al., 1985) and turkeys (Corrier, 1991). Since complement is required for normal phagocytosis, impairment in complement activity may partially explain impairment of phagocytosis in chickens experiencing aflatoxicosis (Gewurz and Suyehira, 1976; Wyatt, 1991).

Chang and Hamilton (1979a) demonstrated reduced chemotactic ability of leucocytes, impaired phagocytosis of heterophils and impaired cellular and serum factors required for optimal phagocytosis in aflatoxicated chickens. Although thrombocytic counts are depressed by dietary aflatoxin (Mohiuddin et al., 1986) their phagocytic activity is not affected by aflatoxin (Chang and Hamilton, 1979b). However, other phagocytic cells (heterophils, macrophages and monocytes) were affected by dietary aflatoxin (Chang and Hamilton, 1979a). Chickens receiving aflatoxin-contaminated diets showed higher susceptibility to Marek’s disease (Edds and Bortell, 1983), infectious bursal disease virus (Giambrone et al., 1978a & b), congenitally acquired salmonellosis (Wyatt and Hamilton, 1975) and duodenal and cecal coccidiosis (Edds et al., 1973) than chickens receiving aflatoxin free diet.
From the aforementioned, it is postulated that aflatoxin interferes with normal function of B and T lymphocytes, rather than causing destruction of these cells (Wyatt, 1991). The impairment of protein synthesis caused by dietary aflatoxin could account for the lack of humoral immunity without the necessity of B and T cell destruction (Wyatt, 1991). Regardless the atrophy of the bursa of fabricius and thymus gland, the apparent alteration of splenic function is also of diagnostic significance and implies alteration in the immunocompetence of birds with aflatoxicosis (Richard et al., 1975).

2.14 Hematological and biochemical alterations
Aflatoxin causes hematopoietic suppression and anemia observed as decreases in total erythrocytes, packed-cell volume and hemoglobin (Reddy et al., 1984; Huff et al., 1986; Mohiuddin et al., 1986). Total leucocytes are increased and differential leucocytic counts vary among studies with concurrent lymphopenia (Tung et al., 1975a; Lanza et al., 1980), monocytoses and heterophilia (Wannop, 1961).

Aflatoxin is known to produce hemolytic anemia by decreasing the circulating mature erythrocytes. Lysis of erythrocytes will result in above the normal levels of cellular debris in circulation (Tung et al., 1975a) and consequently the spleen appear congested because of an unusually high concentration of inorganic iron and debris from the circulation (Wyatt, 1991).

Several biochemical parameters are affected by aflatoxin exposure. Aflatoxin decreases total serum proteins, alpha, beta and gamma globulins, with IgG being more sensitive than IgM (Tung et al., 1975a). Total serum proteins contents are depressed due to reduced values of alpha and beta globulins and albumen, while gamma globulins are affected more variably (Pier, 1973).

Serum lipoproteins, cholesterol, triglycerides, uric acid and calcium are also decreased (Garlich et al., 1973; Doerr et al., 1983; Reddy et al., 1984; Huff et al., 1986). The activity of serum or plasma enzymes has been extensively used as a measure of aflatoxin activity in chickens. Increased activities of sorbitol dehydrogenase, glutamic dehydrogenase, lactate dehydrogenase, alkaline phosphatase, acid phosphatase, aspartate aminotransferase and alanine aminotransferase were reported in aflatoxicated chickens (Dafalla et al., 1987b; Rao and Joshi, 1993; Leeson et al., 1995). The increase in the levels of serum enzymes measured was interpreted as a consequence of hepatocyte degeneration and subsequent leakage of enzymes (Leeson et al., 1995).

Aflatoxin has also shown to alter both the extrinsic and common clotting pathways in chickens. Aflatoxins causes biochemical changes in thromboplastin clotting factors V, VII and X and reduces plasma prothrombin and fibrinogen (Doerr et al., 1976), and consequently increases whole blood clotting and prothrombin times (Doerr et al., 1974). The elevated prothrombin time was considered to be the result of impaired hepatic synthesis of clotting factors caused by the toxication of aflatoxin on the liver cells (Huff et al., 1983).

The activity of some digestive enzymes, the absorption of carotenoid compounds from the gastrointestinal tract, and the metabolism of lipids can be altered by aflatoxin exposure (Leeson et al., 1995). Dietary aflatoxin produced a malabsorption syndrome characterized by steatorrhea, hypocarotenoidemia and decreased concentrations of bile salts and pancreatic lipase, trypsin, amylase and Rnase (Osborne et al., 1982). In another experiment, the specific activities of pancreatic chymotrypsin, amylase and lipase, but not trypsin were increased significantly by aflatoxin (Richardson and Hamilton, 1987).
The effect of aflatoxin on the renal function of broiler chickens was reported by Glahn (1993). Aflatoxin treated birds showed decreased fractional excretion of phosphate, total plasma calcium concentration, decreased total plasma proteins, plasma 25-hydroxy vitamin D and plasma 1, 25-dihydroxy vitamin D.

2.15 Wild life

Birds, fishes and mammals vary among species in susceptibility to aflatoxins. Birds such as bobwhite quail and wild turkey appear to be more susceptible than mammals (Horn et al., 1989). It is difficult to document the extent to which wildlife species are affected because wild animals are free roaming and elusive. In many cases, predators and scavengers may consume dead or dying animals before the dead animals are found by humans (Stewart and Larson, 2002).

Clinical signs of aflatoxicosis in wildlife vary according to the dose received, the time period of exposure, and species of animal. Toxic effects can be divided into acute, subacute and chronic exposures (Stewart and Larson, 2002). Acute effects reflect severe liver disease. Animals may be anemic and may exhibit difficulty in breathing. Sudden death with no clinical signs may occur. Subacute effects may allow animals to live for a longer period of time. These animals have yellow eyes, mucous membranes, or yellowed skin along with abnormalities in blood clotting. Bruising, nose bleeds and hemorrhaging may be observed. Chronic effects are generally related to impaired liver function. Long-term, low-level consumption of aflatoxins may result in reduced feed efficiency, weight loss, lack of appetito and increased receptivity to secondary infectious diseases. Lesions may occur in the liver and other organs and fluid may accumulate in the body cavity.

2.15.1 Fish

Fish have been found susceptible to aflatoxin and trichothecenes. Aflatoxicosis is most prevalent among fishes. The extent of lesions caused by consumption of aflatoxins depends upon the age and species of the fish. Fry are more susceptible to aflatoxicosis than adults and some species of fish are more sensitive to aflatoxins than others (Royes and Yanong, 2002). Rainbow trout are the most sensitive species to aflatoxin. Feeding trout diets containing less than 1 ppb will cause liver tumors in 20 months. (Horn et al., 1989). Diet containing AFB1 at 0.4 ppb for 15 months had a 14% chance of developing tumors. Feeding trout a diet containing 20 ppb for 8 months resulted in 58% occurrence of liver tumors and continued feeding for 12 months resulted in 83% incidence of tumors (Royes and Yanong, 2002).

Deaths quickly occur in 50% of stock if dietary levels of 500 to 1000 ppb are consumed. Warm water fishes such as channel catfish (Ictalurus punctatus) are much less sensitive than rainbow trout, and the level required to cause 50% mortality is approximately 30 times that of rainbow trout (Horn et al., 1989). Channel catfish fed a diet containing purified AFB1 at 10,000 ppb for 10 weeks exhibited decreased growth rate and moderate internal lesions (Royes and Yanong, 2002).

Initial findings associated with aflatoxicosis in fishes include pale gills, impaired blood clotting, poor growth rates or lack of weight gain. Prolonged feeding of low concentrations of AFB1 causes liver tumors, which appear as pale yellow lesions and which can spread to the kidney. Increased in mortality may be observed (Royes and Yanong, 2002).
Aflatoxin can also depress the immune system indirectly through their effect on enestial nutrients in the diet, making fish more susceptible to bacterial, viral and parasitic diseases. Moreover, aflatoxin can cause slow growth rate and reduced weight of the finished product of warm-water fish (Royes and Yanong, 2002).

3. Conclusion

This chapter describes the food sources of aflatoxin contamination and their diseases in human and animals such as cattles, poultry, fish and other wild animals. Quality of food and feed plays the most important role in the farming as its share is 70%. Good quality food and resistant strain of animals can lead to greater production and more profit for the poultry, dairy, fishery henser. However, the acute shortage of chicken, mutton, fish meat has pushed its prices steeply upwards. It is suggested that use of chicks, cow, sheep, fish, dog, horses are resistant to aflatoxicosis, would help in minimizing problem of poor growth rate and poor feed conversion which perhaps are the two most important factors in animal management.

Aflatoxins and Aflatoxicosis in Human and Animals

Aflatoxins – Biochemistry and Molecular Biology is a book that has been thought to present the most significant advances in these disciplines focused on the knowledge of such toxins. All authors, who supported the excellent work showed in every chapter of this book, are placed at the frontier of knowledge on this subject, thus, this book will be obligated reference to issue upon its publication. Finally, this book has been published in an attempt to present a written forum for researchers and teachers interested in the subject, having a current picture in this field of research about these interesting and intriguing toxins.

How to reference
