Numerical Inverse Laplace Transforms for Electrical Engineering Simulation

Lubomír Brančík
Brno University of Technology
Czech Republic

1. Introduction

Numerical inverse Laplace transform (NILT) methods are widely used in various scientific areas, especially for a solution of respective differential equations. In field of electrical engineering many various approaches have been considered so far, but mostly for a single variable (1D NILT), see at least (Brančík, 1999, 2007b; Cohen, 2007; Valsa & Brančík, 1998; Wu et al., 2001) from plenty of papers. Much less attention was paid to multidimensional variable (nD NILT) methods, see e.g. (Hwang at al., 1983; Singhal at al., 1975), useful rather for more complicated electromagnetic systems. The 2D NILT methods, see e.g. (Brančík, 2005, 2007a, 2007b; Hwang & Lu, 1999), can be applied for a transmission line analysis, or nD NILT methods, n ≥ 2, for a nonlinear circuits analysis, if relevant Laplace transforms are developed through a Volterra series expansion, see e.g. (Brančík, 2010a, 2010b, Karmakar, 1980; Schetzen, 2006), to highlight at least a few applications. This paper is focused on the class of NILT methods based on complex Fourier series approximation, their error analysis, their effective algorithms development in a Matlab language, and after all, on their selected applications in field of electrical engineering to show practical usefulness of the algorithms.

2. Multidimensional numerical inverse Laplace transform

An n-dimensional Laplace transform of a real function \( f(t) \), with \( t = (t_1, ..., t_n) \) as a row vector of \( n \) real variables, is defined as (Hwang at al., 1983)

\[
F(s) = \prod_{i=1}^{n} \int_{0}^{\pi} f(t_i) \exp(-st_i T) dt_i,
\]

(1)

where \( s = (s_1, ..., s_n) \) and \( T \) means a transposition. Under an assumption \( |f(t)| < M \exp(a^T) \), with \( M \) real positive and \( a = (a_1, ..., a_n) \) being a minimal abscissa of convergence, and the nD Laplace transform \( F(s) \) defined on a region \( \{ s \in C: \text{Re}[s] > \alpha \} \), with \( \alpha = (\alpha_1, ..., \alpha_n) \) as an abscissa of convergence, and the inequality taken componentwise, the original function is given by an n-fold Bromwich integral

\[
f(t) = \frac{1}{(2\pi)^n} \int_{c_1-j\infty}^{c_1+j\infty} \cdots \int_{c_n-j\infty}^{c_n+j\infty} F(s) \exp(st^T) \prod_{i=1}^{n} dt_i.
\]

(2)
In the papers (Brančík, 2007a, 2007b, 2010b), it was shown for the 1D, 2D, and 3D cases, the rectangular method of a numerical integration leads to an approximate formula whose a relative error is adjustable, and corresponds to the complex Fourier series approximation of a respective dimension. The method has been generalized for an arbitrary dimension \( n \) in the recent work (Brančík, 2011).

### 2.1 Complex Fourier series approximation and limiting relative error

Substituting \( s_i = c_i + j\omega_i \) into (2), and using a rectangular rule of the integration, namely \( \omega_i = m_i\Omega_i \), and \( \Omega_i = \frac{2\pi}{\tau_i} \) as generalized frequency steps, with \( \tau_i \) forming a region of the solution \( t \in [0, \tau_1] \times \cdots \times [0, \tau_n] \), an approximate formula is

\[
\tilde{f}(t) = \exp(\alpha t^T) \left( \prod_{i=1}^{n} \tau_i^{-1} \right) \sum_{m_1=-\infty}^{\infty} \cdots \sum_{m_n=-\infty}^{\infty} F(s) \exp \left( j \sum_{i=1}^{n} m_i\Omega_i t_i \right),
\]

with \( s_i = c_i + j m_i\Omega_i \) \( \forall i \). As is shown in (Brančík, 2011), a limiting relative error \( \delta_M \) of (3) can be controlled by setting \( c = (c_1, \ldots, c_n) \), defining paths of the integration in (2), namely

\[
c_i = \alpha_i - \frac{1}{\tau_i} \ln \left( 1 - \frac{1}{\sqrt{1 + \delta_M}} \right) \approx \alpha_i - \frac{1}{\tau_i} \ln \delta_M / n,
\]

for \( i = 1, \ldots, n \), and while keeping the equalities \( \tau_1(c_1 - \alpha_1) = \cdots = \tau_n(c_n - \alpha_n) \). The simplification in (4) is enabled due to small values \( \delta_M \) considered in practice. The last equation is used for setting up parameters of the \( n \)D NILT method relating them to a limiting relative error \( \delta_M \) required for practical computations.

### 2.2 Practical computational methods

It should be highlighted that the formula (4) is valid, and a relative error supposed is really achievable by the \( n \)D NILT (3), if infinite numbers of terms are used in the series. In practice, it cannot sure be fulfilled, but a suitable technique for accelerating a convergence of infinite series is usable, as is e.g. a quotient-difference (q-d) algorithm (Rutishauser, 1957). Besides, as has been already successfully used for cases of \( n \leq 3 \), the formula (3) can be rearranged to enable using FFT & IFFT algorithms for an effective computation.

#### 2.2.1 Partial ILTs evaluation technique

The technique of practical evaluation of the \( n \)-fold infinite sum (3) follows the properties of the \( n \)-fold Bromwich integral (2), namely we can rearrange it into the form

\[
f(t_1, t_2, \ldots, t_n) = \frac{1}{2\pi j} \int_{c_1 - j\infty}^{c_1 + j\infty} \frac{1}{2\pi j} \int_{c_2 - j\infty}^{c_2 + j\infty} \cdots \frac{1}{2\pi j} \int_{c_n - j\infty}^{c_n + j\infty} F(s_1, s_2, \ldots, s_n) e^{x_1 t_1}ds_1 \cdots e^{x_n t_n}ds_n e^{\sum_i x_i t_i} dt_i,
\]

or shortly

\[
f(t_1, t_2, \ldots, t_n) = L_n^{-1} \left[ L_1^{-1} \left[ \cdots L_2^{-1} \left[ F(s_1, s_2, \ldots, s_n) \right] \cdots \right] \right].
\]

Although the order of the integration may be arbitrary on principle, here the above one will be used for an explanation. Similarly, (3) can be rewritten as
\[\tilde{f}(t_1,t_2,\ldots,t_n) = \frac{e^{\sqrt{\Omega}}}{t_1} \sum_{m_0=-\infty}^{\infty} \frac{e^{\sqrt{\Omega}}}{t_2} \sum_{m_1=-\infty}^{\infty} \cdots \frac{e^{\sqrt{\Omega}}}{t_n} \sum_{m_n=-\infty}^{\infty} F(s_1,s_2,\ldots,s_n) e^{im_0\Omega t_1} \cdots e^{im_n\Omega t_n}, \quad (7)\]

with \(s_i = c_i + jm\Omega\). If we define \(F_{n} \equiv F(s_1,\ldots,s_{n-1},s_n)\) and \(F_0 \equiv f(t_1,\ldots,t_{n-1},t_n)\), then \(n\) consequential partial inversions are performed as

\[\mathbb{L}^{-1}\{F_n\} = F_{n-1}(s_1,\ldots,s_{n-1},t_n), \quad \mathbb{L}^{-1}\{F_{n-1}\} = F_{n-2}(s_1,\ldots,t_{n-1},t_n), \quad \ldots \quad \mathbb{L}^{-1}\{F_1\} = f(t_1,\ldots,t_{n-1},t_n). \quad (8)\]

As is obvious we need to use a procedure able to make the inversion of Laplace transforms dependent on another \(n-1\) parameters, complex in general. Let us denote arguments in (8) by \(p_i = (p_{i1},\ldots,p_{i,n-1},p_{in})\). Then the ILT of the type

\[F_{i-1}(p_{i-1}) = \mathbb{L}^{-1}\{F_i(p_i)\} = \frac{1}{2\pi j} \int_{c_i-j\infty}^{c_i+j\infty} F_i(p_i) e^{p_i t} dp_i \quad (9)\]

can be used \(n\) times, \(i = n,n-1,\ldots,1\), to evaluate (8), with \(p_{n0} = (s_1,\ldots,s_{n-1},s_n)\), \(p_{n-1} = (s_1,\ldots,s_{n-2},s_{n-1},t_n)\), \(p_{n-1} = (s_1,\ldots,t_{n-1},t_n)\), and \(p_{00} = (t_1,\ldots,t_{n-1},t_n)\), while \(p_{ij} = s_j\) for \(j < i\), and \(p_{ij} = t_j\) otherwise. A further technique is based on demand to find the solution on a whole region of discrete points. Then, taking into account \(t_h = kT_i\) in (9), with \(T_i\) as the sampling periods in the original domain, we can write an approximate formula

\[\tilde{F}_{i-1}(p_{i-1}) = \frac{e^{\sqrt{\Omega}T_i}}{t_i} \sum_{m_0=-\infty}^{\infty} \tilde{F}_i(p_i) e^{j2\pi m k T_i/t_i} \quad (10)\]

\(i = n,n-1,\ldots,1\), and with \(\Omega = 2\pi/\tau\) substituted. As follows from the error analysis (Brančič, 2011) a relative error is predictable on the region \(O_{err} = [0,\pi] \times \cdots \times [0,\pi]\). For \(k = 0,1,\ldots,M-1\), \(i = 1,\ldots,n\), a maximum reachable region is \(O_{max} = [0,(M-1)T_i] \times \cdots \times [0,(M_{n-1}-1)T_n]\). Thus, to meet the necessary condition \(O_{max} \subseteq O_{err}\), we can set up fittingly \(\tau = M T_i, i = 1,\ldots,n\). In practice, a region of the calculation is chosen to be \(O_{calc} = [0,T_{calc}] \times \cdots \times [0,T_{calc}]\), with \(T_{calc} = (M_i/2-1)T_i\), \(i = 1,\ldots,n\), to provide certain margins.

### 2.2.2 FFT, IFFT, and quotient-difference algorithms utilization

As is shown in (Brančič, 2007a, 2007b, 2010c), the discretized formula (10) can be evaluated by the FFT and IFFT algorithms, in conjunction with the quotient-difference (q-d) algorithm for accelerating convergence of the residual infinite series, see following procedures.

To explain it in more detail, let us consider an \(r\)-th cycle in gaining the original function via (9), i.e. \(F_{r-1}(p_{r-1}) = \mathbb{L}^{-1}\{F_r(p_r)\}\). For its discretized version (10) we have

\[\tilde{F}_{r-1}(s_1,\ldots,kT_i,\ldots,t_n) = \frac{e^{\sqrt{\Omega}T_i}}{\tau_i} \sum_{m_0=-\infty}^{\infty} \tilde{F}_r(s_1,\ldots,c_r + jm\frac{2\pi}{\tau_i},\ldots,t_n) e^{j2\pi m k T_i/t_i}. \quad (11)\]

The above stated formula can be decomposed and expressed also as

www.intechopen.com
\[
\tilde{F}_{r^{-1}}(s_1, \ldots, kT, \ldots, t_n) = e^{c^2kT} \left[ \sum_{m=0}^{M-1} \tilde{F}_r^{(m)} z_{-m}^r + \sum_{m=0}^{M-1} \tilde{G}_r^{(m)} z_{-m}^r + \sum_{m=0}^{M-1} \tilde{F}_r^{(m)} z_{-k}^r + \sum_{m=0}^{M-1} \tilde{G}_r^{(m)} z_{-k}^r - \tilde{F}_r^{(0)} \right],
\]

(12)

where individual terms are defined as

\[
M_r = 2^K, \text{ integer,}
\]

\[
\tilde{F}_r^{(m)} = \tilde{F}_r(s_1, \ldots, c_r, \pm jn2\pi / r, \ldots, t_n),
\]

\[
\tilde{G}_r^{(m)} = \tilde{G}_r^{(m)}(\pm M_{r+1}),
\]

\[
z_{\pm k} = \exp(\pm j2\pi kT / r),
\]

when \( z_{\pm k}^M = e^{\pm j2\pi k} = 1, \forall k \), has been considered, and \( r = M_nT \).

As is evident the first and the third finite sum of (12) can be evaluated via the FFT and IFFT algorithms, respectively, while \( 2P+1 \) terms from the infinite sums are used as the input data in the quotient-difference algorithm (Macdonald, 1964; McCabe, 1983; Rutishauser, 1957).

We can replace the above infinite power series by a continued fraction as

\[
\sum_{m=0}^{\infty} \tilde{G}_r^{(m)} z_{\pm k}^m = d_0/(1 + d_1 z_{\pm k} / (1 + \cdots + d_{2P} z_{\pm k})), \forall k,
\]

(14)

which gives much more accurate result than the original sum truncated on \( 2P+1 \) terms only.

The q-d algorithm process can be explained based on a lozenge diagram shown in Fig. 1.

Fig. 1. Quotient-difference algorithm lozenge diagram

The first two columns are formed as

\[
ed_{0}^{(i)} = 0, \quad i = 0, \ldots, 2P,
\]

\[
ed_{1}^{(i)} = \tilde{G}_r^{(i+1)} / \tilde{F}_r^{(i)}, \quad i = 0, \ldots, 2P - 1,
\]

(15)

while the successive columns are given by the rules

\[
ed_{j}^{(i)} = ed_{j-1}^{(i+1)} / ed_{j-1}^{(i+1)}, \quad i = 0, \ldots, 2P - 2j, \quad \text{for } j = 1, \ldots, P,
\]

\[
ed_{j}^{(i)} = ed_{j-1}^{(i-1)} / ed_{j-1}^{(i-1)}, \quad i = 0, \ldots, 2P - 2j - 1, \quad \text{for } j = 2, \ldots, P.
\]

(16)
Then, the coefficients $d_m, m = 0, \ldots, 2P$, in (14) are given by

$$
d_0 = \tilde{C}_0^0, \quad d_{2j-1} = -q_j^0, \quad d_{2j} = -e_j^0, \quad j = 1, \ldots, P.
$$

For practical computations, however, the recursive formulae stated below are more effective to be used (DeHoog et al., 1982). They are of the forms

$$
A_m(z_{2k}) = A_{m-1}(z_{2k}) + d_m z_{2k} A_{m-2}(z_{2k}), \quad B_m(z_{2k}) = B_{m-1}(z_{2k}) + d_m z_{2k} B_{m-2}(z_{2k}),
$$

for $m = 1, \ldots, 2P, \forall k$, with the initial values $A_1 = 0, B_1 = 1, A_0 = d_0$ and $B_0 = 1$. Then, instead of the continued fraction (14), we can write

$$
\sum_{m=0}^{2P} \tilde{C}_r^{(zm)} z_{2k} = A_{2P}(z_{2k})/B_{2P}(z_{2k}), \quad \forall k.
$$

The q-d algorithm is a very efficient tool just for a power series convergence acceleration, here enabling (7) to achieve a relative error near its theoretical value defined by (4), see the following examples.

### 2.3 Matlab listings and experimental errors evaluation

In this part experimental verifications of the nD NILT theory above will first be presented, for one to three dimensional cases, i.e. $n \leq 3$. For such dimensions the Matlab functions have been developed and errors stated on a basis of some sample images with known originals. The Matlab listings of basic versions of the NILT functions are provided, together with examples of their right calling. Another Matlab listings will be discussed in more detail later, in the chapter with practical applications.

#### 2.3.1 One-dimensional NILT

In case of the 1D inverse LT, a well-known Bromwich integral results from (2), namely

$$
f(t) = \frac{1}{2\pi} \int_{c-i\infty}^{c+i\infty} F(s) e^{st} \, ds,
$$

where indexes 1 were omitted. By using the theory above a path of the numerical integration is stated according to (4), leading to

$$
c = \alpha - \frac{1}{\tau} \ln \left(1 - \frac{1}{1 + \delta_M}\right) = \alpha + \frac{1}{\tau} \ln \left(1 + \frac{1}{\delta_M}\right) = \alpha - \frac{1}{\tau} \ln \delta_M.
$$

In contrast to most other approaches, the 1D NILT method described here enables to treat complex images resulting in complex originals as no real or imaginary parts are extracted during an evaluation process. It can be useful in some special applications, not only in the electrical engineering. We can show it on a simple transform pair

$$
F(s) = \frac{1}{s-j\omega} = \frac{s}{s^2 + \omega^2} + j \frac{\omega}{s^2 + \omega^2} \quad \mapsto \quad f(t) = e^{j\omega t} = \cos \omega t + j \sin \omega t.
$$

www.intechopen.com
Of course, when preprocessing the transform to arrange it to a Cartesian form, as is shown on the right sides in (22), the result could be by getting the real and imaginary parts separately, by using an arbitrary NILT method. Here, however, no symbolic manipulations are needed in advance, and F(s) enters the NILT function in its basic form as a whole. A Matlab language listing is shown in Tab. 1, where the relative error needed is marked by Er and is subject to a change if necessary, similarly as the minimal abscissa of convergence (exponential order) α, alfa, numbers of points for the resultant solution, M, and for the q-d algorithm, P. If only real transforms F(s) are considered the bottom line in the listing can be inactivated. The NILT function is called from a command line as follows: niltc('F', tm); where F is a name of another function in which the F(s) is defined, and tm marks an upper limit of the original variable t. In our case, and for $\omega = 2\pi$, this function can have a form

```matlab
function f=expc(s)
f=1./(s-2*pi*j);
```

Table 1. Matlab listing of 1D NILT method accepting complex arguments

As is obvious, the Laplace transform must be defined to enable Matlab array processing, i.e. element-by-element array operators have to be used. Thus, the calling our function can look like

```matlab
niltc('expc', 4);
```

if the function is saved under the same name, expc, or it is placed inside the M-file with own NILT function (Tab. 1), following always its body. Alternatively, the calling can look like $[ft, t] = niltc('F', tm)$; if respective variables in the brackets are to be saved in the memory after the function finishes.

www.intechopen.com
Graphical results and corresponding errors are shown in Fig. 2. Because the originals are bounded by values ±1, and \( \alpha = 0 \), we can see the errors satisfy (21) very well (\( \delta_M = 10^{-10} \) was considered), excluding only beginning of the interval.

![Graphical results](image)

Fig. 2. Numerical inversion leading to complex original \( f(t) = \exp(j\omega t) \)

Another test functions are considered in Tab. 2, with numerical results shown in Fig. 3. As is again obvious from Fig. 3 the relative errors satisfy theoretical expectations, with an exception of vicinities of discontinuities.

Table 2. Test Laplace transforms for errors evaluation

### 2.3.2 Two-dimensional NILT

In case of the 2D inverse LT, a two-fold Bromwich integral results from (2), namely

\[
f(t_1,t_2) = -\frac{1}{4\pi} \int_{c_1 - j\infty}^{c_1 + j\infty} \int_{c_2 - j\infty}^{c_2 + j\infty} F(s_1,s_2) e^{s_1t_1 + s_2t_2} ds_1 ds_2,
\]

and by using the theory above the paths of numerical integrations are stated based on (4) as

\[
c_i = \alpha_i - \frac{1}{\tau_i} \ln \left( 1 - \frac{1}{\sqrt{1 + \delta_M}} \right) = \alpha_i - \frac{1}{\tau_i} \ln \frac{\delta_M}{2}, \quad i = 1, 2.
\]
Nevertheless, the Laplace transform variables and the original variables have changed in this listing as $s_1 \rightarrow p$, $s_2 \rightarrow q$, and $t_1 \rightarrow x$, $t_2 \rightarrow y$, respectively, which simplified a writing. The parameters are then indexed in compliance with these new notations. Besides, numbers of points used to plot three-dimensional graphical results are set by $xpl$ and $ypl$.

For the same reasons as at the 1D NILT, the 2D NILT method discussed here enables to treat complex images of two variables resulting in complex originals. We will show it on a simple transform pair

$$F(s_1, s_2) = \frac{1}{(s_1 - j\omega_1)(s_2 - j\omega_2)} \mapsto f(t_1, t_2) = e^{i(\alpha_1 t_1 + \alpha_2 t_2)}. \quad (25)$$

After rearranging the above equation, we can also write

$$F(s_1, s_2) = \frac{s_1 s_2 - \omega_1 \omega_2}{(s_1^2 + \omega_1^2)(s_2^2 + \omega_2^2)} + j \frac{\omega_2 s_1 + \omega_1 s_2}{(s_1^2 + \omega_1^2)(s_2^2 + \omega_2^2)} \mapsto f(t_1, t_2) = \cos(\alpha_1 t_1 + \alpha_2 t_2) + j \sin(\alpha_1 t_1 + \alpha_2 t_2) \quad (26).$$

The 2D NILT function is called from a command line as follows: \texttt{nilt2c('F',xm,ym);} where \texttt{F} is a name of another function in which the $F(p,q)$ is defined, and \texttt{xm} and \texttt{ym} mark upper limits of the original variables $x$ and $y$. In our case, and for $\omega_1 = \omega_2 = 2\pi$, this function can have a form

function $f=\text{exp2c}(p,q)$
$\ f = 1./((p-2*pi*1j)./(q-2*pi*1j));$

and its calling can look like \texttt{nilt2c('exp2c', 3, 3)}; with graphical results in Fig. 4. As the originals are bounded by values $\pm 1$, and $\alpha_1 = \alpha_2 = 0$, we can see the errors satisfy (21) very well ($\delta_M = 10^{-8}$ was considered), excluding beginnings of the 2D region.
Another simple example shows a shifted 2D unit step, with different shifts along the axis. A corresponding transform pair is

$$F(s_1,s_2) = \frac{\exp(-2s_1 - s_2)}{s_1 s_2} \quad \mapsto \quad f(t_1,t_2) = \mathbb{1}(t_1 - 2, t_2 - 1).$$  \hspace{1cm} (27)$$

In this case, a displaying imaginary part gives a zero plane, and the respective line in the 2D NILT function can be inactivated. The graphical results are depicted in Fig. 5, including an absolute error. The respective Matlab function can be of a form
function \( f = \text{step2}(p, q) \)
\( f = \exp(-2*p-q) ./ p ./ q; \)

and called as \texttt{nilt2c('step2',4,4)}; with the results theoretically expected.

Fig. 4. Numerical inversion leading to complex original \( f(t_1,t_2) = \exp(\omega(t_1+t_2)) \)

Fig. 5. Numerical inversion leading to shifted 2D unit step \( f(t_1,t_2) = \mathbb{1}(t_1-2,t_2-1) \)

### 2.3.3 Three-dimensional NILT

In case of the 3D inverse LT, a three-fold Bromwich integral results from (2), namely

\[
f(t_1,t_2,t_3) = \frac{1}{8\pi^3} \int_{c_3-j\infty}^{c_3+j\infty} \int_{c_2-j\infty}^{c_2+j\infty} \int_{c_1-j\infty}^{c_1+j\infty} F(s_1,s_2,s_3) e^{s_1t_1+s_2t_2+s_3t_3} ds_3 ds_2 ds_1,
\]

and by using the theory above the paths of numerical integrations are stated based on (4) as

www.intechopen.com
\[ c_i = \frac{1}{\tau_i} \ln \left( 1 - \frac{1}{1 + \delta_i} \right) \approx \frac{1}{\tau_i} \ln \frac{\delta_i}{3}, \quad i = 1, 2, 3. \]  

(29)

Here only experimental results will be shown to verify an accuracy of the method. A Matlab language listing looks similarly like for the 2D NILT case, but the partial NILT subfunction is called once more, and respective arrays dimensions are enlarged. Original functions corresponding to 3D Laplace transforms cannot be displayed graphically as a whole, of course. However, for one variable chosen as constant, it is possible to display three respective two-dimensional cuts. It will be demonstrated on the example of 3D shifted unit step

\[ \exp(-s_1 - 2s_2 - 3s_3) \quad \mapsto \quad f(t_1 - 1, t_2 - 2, t_3 - 3), \]  

(30)

with different values of shifts along respective coordinates so that correctness of results can easily be identified, see Fig. 6. Errors again correspond to theoretically expected ones.

Fig. 6. Numerical inversion leading to shifted 3D unit step \( f(t_1, t_2, t_3) = 1(t_1 - 1, t_2 - 2, t_3 - 3) \)

3. Application of NILT algorithms to electrical engineering simulation

In this chapter some examples of the application of the NILT algorithms developed relating to problems of electrical engineering simulation are presented. First, the 1D NILT method is applied for the solution of transient phenomena in linear electrical circuits with both lumped and distributed parameters. This well-known approach is usable wherever linear ordinary differential equations (ODE) are transformed into algebraic ones so that an inverse Laplace transform can be considered. Then the 2D NILT method is utilized to solve transient phenomena on transmission lines (TL) after relevant telegraphic equations (a type of partial differential equations (PDE)) are transformed into algebraic ones by a 2D Laplace transform. In this way voltage and/or current distributions along the TL wires can be determined in a single calculation step. Finally, the utilization of the 1D to 3D NILTs to weakly nonlinear
electrical circuits solution is discussed. In this case the relevant nonlinear ODEs describing the circuit are expanded into Volterra series which respective NILTs are applied on.

3.1 One-dimensional NILT algorithm application
3.1.1 Preliminary example based on lumped parameter circuit
A simple example demonstrating the application of the basic 1D NILT algorithm in Tab. 1 is shown in Fig. 7. This really initiatory linear electrical circuit was chosen with an intention to be also considered later, in chapter 3.3.1, as a nonlinear circuit, with $G_2$ being a nonlinear element. In this way one will be able to compare results and make some conclusions.

\[
\begin{align*}
\dot{i}(t) & \quad C \quad i_c(t) \quad i_{G_1}(t) \quad i_{G_2}(t) \quad v(t)
\end{align*}
\]

Fig. 7. Linear reactive electrical circuit of the 1st order

Denoting $G = G_1 + G_2$, the 1st-order linear ODE has a form

\[
C \frac{dv(t)}{dt} + Gv(t) = i(t),
\]

with a Laplace-domain solution

\[
V(s) = \frac{I(s) + Cv(0)}{G + sC},
\]

with an initial condition $v(0)$. Even if the above circuit is very simple a finding time-domain solution could be rather work-intensive if the circuit is excited from some non-trivial input current waveform. A few basic examples are given in Tab. 4, specially the first one results in a transient characteristic of the circuit.

Table 4. Exciting current source waveforms and their Laplace transforms

For the above examples, of course, time-domain analytical solutions can be found e.g. based on a Heaviside formula. The 1D NILT function graphical results, under a condition $v(0) = 0$, and considering values $C = 1\, \text{mF}$, $G_1 = G_2 = 10\, \text{mS}$, and $I_0 = 1\, \text{mA}$, are shown in Fig. 8. The above waveforms can be got by either successive application of a basic version of the 1D NILT method according to Tab. 1, or a generalized 1D NILT function, its vector version, can be used to process all the computations in parallel. This function is shown in Tab. 5.

    case 'p1', plott1(t,ft); case 'p2', plott2(t,ft); case 'p3', plott3(t,ft); otherwise display('Invalid Plot'); end

Table 5. Matlab listing of vector version of 1D NILT method

Here one more parameter depict is used to define a method of plotting individual items from a set of originals. The 1D NILT function is called as niltcv('F',tm,'depict'); where 'depict' is a text string 'p1', 'p2', or 'p3', see Tab. 6 for more details.
Table 6. Matlab listing of plotting functions for vector version of 1D NILT method

To get e.g. the right part of Fig. 8, that is the voltage response of the circuit in Fig. 7, the calling the 1D NILT function looks like

\[
\text{niltcv('V4',1,'p1')}
\]

where

\[
V4
\]
denotes a name of the function defining individual responses as follows:

\[
\text{function } f = \text{V4}(s)
\]

\[
I_0 = 1e^{-3}; C = 1e^{-3}; G = 2e^{-2};
\]

\[
f(1,:) = \frac{I_0}{s/(G+s*C)};
\]

\[
f(2,:) = \frac{I_0}{(s+5)/(G+s*C)};
\]

\[
f(3,:) = \frac{2\pi I_0}{s^2+4\pi^2}/(G+s*C);
\]

\[
f(4,:) = \frac{s^2 I_0}{s^2+4\pi^2}/(G+s*C);
\]

In this case the lines causing the imaginary parts plotting can be inactivated. The remaining plotting functions will be explained in the next chapter.

3.1.2 Application for transmission line simulation

Here, the 1D NILT algorithms will be used to simulate voltage and/or current distributions along transmission lines (TL), as shown on a Laplace-domain TL model in Fig. 9. As is well known, this model results from the application of a Laplace transform, with respect to time, on a pair of partial differential equations (telegraphic) of the form

\[
0 \frac{\partial v(t,x)}{\partial t} + \frac{\partial i(t,x)}{\partial x} = \frac{R_0 i(t,x) + L_0}{C_0 v(t,x) + C_0} \frac{\partial v(t,x)}{\partial t} + \frac{R_0 i(t,x) + L_0}{C_0 v(t,x) + C_0} \frac{\partial i(t,x)}{\partial t},
\]

with \(R_0\), \(L_0\), \(C_0\), and \(C_0\) as per-unit-length (p.u.l.) parameters, being constant for uniform TLs, and with a length \(l\).

When considering zero initial voltage and current distributions, \(v(0,x) = 0\) and \(i(0,x) = 0\), and incorporating boundary conditions, we get the Laplace-domain solution in the forms

\[
V(s,x) = V_i(s) \frac{Z_c(s)}{Z_c(s) + Z_i(s)} \frac{e^{-\tau(s)x} + \rho_1(s)e^{-\tau(s)[2l-x]}}{1 - \rho_1(s)\rho_2(s)e^{-2\tau(s)}},
\]

\[
I(s,x) = V_i(s) \frac{1}{Z_c(s) + Z_i(s)} \frac{e^{-\tau(s)x} - \rho_1(s)e^{-\tau(s)[2l-x]}}{1 - \rho_1(s)\rho_2(s)e^{-2\tau(s)}}.
\]
Fig. 9. Laplace-domain model of transmission line with linear terminations

where $Z_c(s)$ and $\gamma(s)$ are a characteristic impedance and a propagation constant, respectively,

$$Z_c(s) = \frac{R_0 + sL_0}{G_0 + sC_0}, \quad \gamma(s) = \sqrt{(R_0 + sL_0)/(G_0 + sC_0)}, \quad (36)$$

and $\rho_1(s)$ and $\rho_2(s)$ are reflection coefficients at the TL beginning and end, respectively,

$$\rho_1(s) = \frac{Z_1(s) - Z_c(s)}{Z_1(s) + Z_c(s)}, \quad \rho_2(s) = \frac{Z_2(s) - Z_c(s)}{Z_2(s) + Z_c(s)}. \quad (37)$$

In a general case of lossy TLs, the time-domain solutions cannot be found by an analytical method, thus the only way is to use some numerical technique.

As an example, let us consider the TL of a length $l = 1m$, with p.-u.-l. parameters $R_0 = 1\Omega$, $L_0 = 600\mu H$, $G_0 = 2\text{mS}$, and $C_0 = 80\text{pF}$, terminated by resistive elements $Z_1 = 10\Omega$, $Z_2 = 1\text{k}\Omega$, and excited by the voltage source waveform $V_i(t) = \sin(\pi/2 \cdot 10^{-9})$, $0 \leq t \leq 2 \cdot 10^{-9}$, and $V_i(t) = 0$, otherwise, with the Laplace transform

$$V_i(s) = \frac{2\pi^2 \left[1 - \exp(-2 \cdot 10^{-9}s)\right]}{s\left(2 \cdot 10^{-9}s\right)^2 + 4\pi^2}. \quad (38)$$

The Fig. 10 shows time dependences at the beginning, the centre, and the end of the TL, while the 1D NILT is called as niltcv('Vs',4e-8,'pl'); where the function Vs is defined as

```matlab
function f=Vs{s}
l=1; x=[0,1/2,1];
R0=1e-3; L0=600e-9; G0=2e-3; C0=80e-12;
Zi=10; Z2=1e3;
Vi=2*pi^2*(1-exp(-2e-9*s))./((2e-9*s).^2+4*pi^2);
Z=R0+1i*L0; Y=G0+s*C0; Zc=sqrt(Z./Y); gam=sqrt(Z.*Y);
rol=(Z1-Zc)./(Z1+Zc); ro2=(Z2-Zc)./(Z2+Zc);
Ks=Vi./(Zi+Zc)./(1-rol.*ro2.*exp(-gam*t));
for k=1:length(x)
  f(k,:)=Ks.*Zc.*(exp(-gam*t(k))+rol2.*exp(-gam*(2*l-x(k))));
end
```

Similarly, current waveforms can be computed by the above function slightly modified according to (35). Both waveforms are depicted in Fig. 10.

Finally, it will be shown, how to obtain three-dimensional graphical results representing voltage and current distributions along the TL. Besides a possibility to use the for cycle, as
shown in the function $V_s$ above, another method based on 3D arrays will be applied, see the function $V_{sx}$ below:

\begin{verbatim}
function f=Vsx(s)
    global x;
    l=1;
    Ro=1e-3; Lo=600e-9; Go=2e-3; Co=80e-12;
    Zi=10; Z2=1e3;
    x=linspace(0,l,65);  % 65 points along TL chosen
    [S,X]=meshgrid(s,x);
    Vi=2*pi^2*(1-exp(-2e-9*S))./S./((2e-9*S).^2+4*pi^2);
    Z=Ro+S*Lo; Y=Go+S*Co; Zc=sqrt(Z./Y); gam=sqrt(Z.*Y);
    ro1=(Zi-Zc)./(Zi+Zc); ro2=(Z2-Zc)./(Z2+Zc);
    Ks=Vi./(Zi+Zc)./(1-ro1.*ro2.*exp(-2*gam*l));
    f=Ks.*Zc.*(exp(-gam.*X)+ro2.*exp(-gam.*(2*l-X)));
end
\end{verbatim}

In this case, the 1D NILT algorithm in Tab. 5 is called as niltcv('Vsx',2e-8,'p3'); that is the plot3 function is used for the plotting, see Tab. 6, and a time limit is half of that in Fig. 10 to get well-observable results. Again, the current distributions can be gained via the above function slightly modified according to (35). Both 3D graphs are depicted in Fig. 11.

3.2 Two-dimensional NILT algorithm application

A two-dimensional Laplace transform can generally be used for the solution of linear partial differential equations with two variables. The advantage is that we get completely algebraic
equations leading to much easier solution in the Laplace domain. A final step in the solution is then the utilization of the 2D NILT algorithm to get results in the original domain. Such a possibility will be shown on the example of telegraphic equations describing transmission lines, and results will be compared with the 1D NILT approach.

### 3.2.1 Application for transmission line simulation

Herein, rather less conventional approach for the simulation of voltage and/or current distributions along the TLs will be discussed. As is obvious from the telegraphic equations (33) they can be transformed not only with respect to the time \( t \), which was matter of the previous paragraph, but also with respect to the geometrical coordinate \( x \) to get completely algebraic equations. After performing such the Laplace transforms, incorporating boundary conditions given by the terminating circuits, and considering again zero initial voltage and current distributions, \( v(0,x) = 0 \) and \( i(0,x) = 0 \), we get (Valsa & Brancík, 1998b)

\[
V(s,q) = \frac{qV_i(s) - \gamma(s)Z_c(s)I_i(s)}{q^2 - \gamma^2(s)}, \quad (39)
\]

\[
I(s,q) = \frac{qI_i(s) - \gamma(s) V_i(s)}{q^2 - \gamma^2(s)}, \quad (40)
\]

where \( V_i(s) = V(s,0) \) and \( I_i(s) = I(s,0) \) are given by (34) and (35), respectively, see also Fig. 9. Thus the 2D NILT function according to Tab. 3 can be called as \texttt{nilt2c('Vsq',2e-8,1)}; leading to the same graphical results as are shown in Fig. 11. The function \texttt{Vsq} can be of the form as stated below. The current distribution is obtained via the same function slightly modified according to (40).

```matlab
function f=Vsq(s,q)
l=1; Zi=10; Z2=1e3;
Ro=1e-3; Lo=600e-9; Co=80e-12;
Vi=2*pi^2*(1-exp(-2e-9*s))./s./((2e-9*s).^2+4*pi^2);
Z=Ro+s*Lo; Y=Go+s*Co; Zc=sqrt(Z./Y); gam=sqrt(Z.*Y);
rol=(Zi-Zc)./(Zi+Zc); ro2=(Z2-Zc)./(Z2+Zc);
Ks=Vi./(Zi+Zc)./(1-rol.*ro2.*exp(-2*gam*l));
V1=Ks.*Zc.*(1+ro2.*exp(-2*gam*l));
I1=Ks.*(1-rol.*exp(-2*gam*l));
f=(q.*V1-Zc.*gam.*I1)./(q.^2-gam.^2);
```

One can notice an interesting thing, namely getting both voltage and current graphs by a single computation step. It is enabled by putting together the voltage and current transforms forming respectively real and imaginary parts of an artificial complex transform, and letting active the program command for the plotting the imaginary part of the original function, see Tab. 3. In our example, if the bottom line in the \texttt{Vsq} function is changed to

```matlab
f=(q.*V1-Zc.*gam.*I1)+j*(q.*I1-gam./Zc.*V1)./(q.^2-gam.^2);
```

then both graphs in Fig. 11 are obtained simultaneously. The same possibility exists for the 1D NILT functions discussed earlier. There is no obvious physical meaning of such artificial complex transforms, it is only a formal tool for inverting two transforms in parallel instead.
3.3 Multidimensional LT in nonlinear electrical circuits simulation

As is known some classes of nonlinear systems can be described through a Volterra series expansion, accurately enough from the practical point of view, when a response \( v(t) \) to a stimulus \( i(t) \) has a form (Schetzen, 2006)

\[
v(t) = \sum_{n=1}^{\infty} v_n(t),
\]

where the terms of the infinite sum are

\[
v_n(t) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} h_n(\tau_1, \tau_2, \ldots, \tau_n) \prod_{k=1}^{n} i(t - \tau_k) d\tau_k,
\]

with \( h_n(\tau_1, \tau_2, \ldots, \tau_n) \) as an \( n \)-th order Volterra kernel, called as a nonlinear impulse response as well. The Fig. 12 shows these equations in their graphical form.

By introducing new variables, \( t_1 = t_2 = \ldots = t_n = t \), and by using the \( n \)-dimensional Laplace transform (1), the \( n \)-fold convolution integral (42) leads to a Laplace domain response

\[
V_n(s_1, s_2, \ldots, s_n) = H_n(s_1, s_2, \ldots, s_n) \prod_{k=1}^{n} I(s_k),
\]

with \( H_n(s_1, s_2, \ldots, s_n) \) as a nonlinear transfer function.

Fig. 12. Nonlinear system response via Volterra series expansion

A few methods are at disposal to find the transfer function for a given nonlinear system, like a harmonic input method, e.g. (Bussgang et al., 1974; Karmakar, 1980). Further procedure is usually based on the association of variables, (J. Debnath & N.C. Debnath, 1991; Reddy & Jagan, 1971), transforming \( V_n(s_1, s_2, \ldots, s_n) \) into the function of a single variable \( V_n(s) \), and enabling to use a one-dimensional ILT to get the required terms \( v_n(t) \) in (41). In contrast to this procedure, it is also possible to determine the terms \( v_n(t_1, t_2, \ldots, t_n) \) by the use of the \( n \)-dimensional ILT, considering \( t_1 = t_2 = \ldots = t_n = t \) in the result as a final step. That is why the above NILT procedures can be adapted in this respect being able to serve as a tool for the nonlinear circuits transient simulation.
3.3.1 Utilization of 1D to 3D NILTs for nearly nonlinear circuits

The utilization of the NILT methods developed, up to three-dimensional case, will be shown on the solution of a nearly nonlinear circuit in Fig. 13. As can be observed this is just Fig. 7 modified to introduce a nonlinearity via $G_2$ conductance.

![Electrical circuit with nonlinear resistive element $G_2$](image)

Assuming a square nonlinearity, a circuit equation is

$$C_0 \frac{dv(t)}{dt} + G_1 v(t) + G_2 v^2(t) = i(t).$$  \hspace{1cm} (44)

By using the harmonic input method, and limiting the solution on the first three terms only, we get the nonlinear transfer functions for (43) as

$$H_1(s_i) = (s_i C + G_1)^{-1},$$  \hspace{1cm} (45)

$$H_2(s_1, s_2) = -G_2 H_1(s_1) H_1(s_2) H_1(s_1 + s_2),$$  \hspace{1cm} (46)

$$H_3(s_1, s_2, s_3) = \frac{G_2}{3} [H_1(s_1) H_2(s_2, s_3) + H_1(s_2) H_2(s_1, s_3) + H_1(s_3) H_2(s_1, s_2)] H_1(s_1 + s_2 + s_3).$$  \hspace{1cm} (47)

Let us use an exciting current and its Laplace transform as

$$i(t) = I_0 e^{-at} \Rightarrow I(s) = \frac{I_0}{s + a},$$  \hspace{1cm} (48)

$a \geq 0$. The substitution (45) – (48) into (43) gives us respective Laplace-domain responses which will undergo the 1D, 2D and 3D NILT algorithms, respectively. We can write

$$v(t) = v_1(t) + v_2(t) + v_3(t) = v_1(t) \bigg|_{t=0}^{t=t_3} + v_2(t_1, t_2) \bigg|_{t_1=t_2=t_3} + v_3(t_1, t_2, t_3) \bigg|_{t_1=t_2=t_3} = L_1^{-1} [V_1(s_i)]_{t_3} + L_2^{-1} [V_2(s_1, s_2)]_{t_3} + L_3^{-1} [V_3(s_1, s_2, s_3)]_{t_3},$$  \hspace{1cm} (49)

with $L_k^{-1}$ as a $k$-dimensional ILT. Thereby, a time-consuming association of ILT can be omitted, e.g. (Wambacq & Sansen, 2010). Individual terms $v_k(t)$ are depicted in Fig. 14, for values agreeing with the linear circuit version in Fig. 7. The current $i(t)$ is defined by $a = 0$ (a unit step), and $a = 5$ (an exponential impulse), compare the first two columns in Tab. 4. The resultant voltage responses computed according to (49) are shown in Fig. 15, including relative errors, where also dependences on Volterra series orders are presented. The relative errors above were computed via a Matlab ODE45 Runge-Kutta function applied directly to the nonlinear ODE (44). As expected, more Volterra terms lead to more accurate results, see also (Brančík, 2009) where up to 2nd-order terms were considered, and respective Matlab listings are presented.
Fig. 14. Numerical inversions leading to voltage response Volterra series terms
Numerical Inverse Laplace Transforms for Electrical Engineering Simulation

4. Conclusion

The paper dealt with a specific class of techniques for the numerical inversion of Laplace transforms, namely based on a complex Fourier series approximation, and connected with a quotient-difference algorithm to accelerate the convergence of infinite series arising in the approximate formulae. The 1D to 3D NILT techniques have been programmed in the Matlab language (R2007b), and most important ones provided as the Matlab function listings. To guide readers all the algorithms were explained on selected examples from field of electrical engineering, including right callings of the functions. In contrast to most others the NILT methods here developed are utilizable to numerically invert complex Laplace transforms, leading to complex originals, which can be useful for some special purposes. As has resulted from error analyses the accuracies range relative errors from $10^{-8}$ to $10^{-10}$ without difficulties which is acceptable for most of practical needs. Based on Matlab functions presented, one could further generalize a vector version of the 1D NILT function towards a matrix one, enabling e.g. to simulate multiconductor transmission line systems, as is shown in (Brančík, 1999), where, however, an alternative technique, so-called ε algorithm, has been applied to accelerate the convergence of infinite series. According to the author’s knowledge, the paper presented ranks among few summary works describing multidimensional NILT techniques, covering Matlab listings beyond, based just on a complex Fourier series approximation, and in conjunction with the quotient-difference algorithm, which seems to be more numerically stable compared to the ε algorithm mentioned above.

6. References

The book presents several approaches in the key areas of practice for which the MATLAB software package was used. Topics covered include applications for: - Motors - Power systems - Robots - Vehicles. The rapid development of technology impacts all areas. Authors of the book chapters, who are experts in their field, present interesting solutions of their work. The book will familiarize the readers with the solutions and enable the readers to enlarge them by their own research. It will be of great interest to control and electrical engineers and students in the fields of research the book covers.
