1. Introduction

Hypothyroidism is relatively a common disease worldwide. Overall prevalence in adults in the United States is 4.6%. (Golden et al., 2009) It can present as mild/subclinical form or overt hypothyroidism with a prevalence of 4.3% and 0.3% of adult populations, respectively. (Golden et al., 2009) Thyroid hormone deficiency has been linked to increased risk of cardiovascular morbidities and mortalities. (McQuade et al., 2011, Resta et al., 2004) Respiratory system like other body systems and organs is affected by hypothyroidism. The spectrum of diseases involvement can range from mild dyspnea to more severe and life-threatening respiratory failure. Several pathophysiological mechanisms are responsible for the compromise in the respiratory system including reduction in central respiratory drive, respiratory muscle weakness and sleep-related breathing disorders (SBD). (Duranti et al., 1993, Saarresranta and Polo, 2002, Curnock et al., 1999) Hypothyroidism is characterized by mucopolysaccharides accumulation in the dermis, hypopharynx, tongue and other tissues. (Skatrud et al., 1981, Orr et al., 1981) In its most severe form (myxedema), patients typically present with hypothermia, hypercapnia, hypotension and bradycardia. Both hypothyroidism and obstructive sleep apnea (OSA) share common signs and symptoms. Increased fatigue and sleepiness, decreased cognitive function, decreased libido, obesity and depressed mood are common findings in both disorders. (Grunstein et al., 1993, Misiolek M and 2007, Chan et al., 2010) Periorbital edema and pedal edema are other common findings in patients with either disorder. Nevertheless, snoring which is a hallmark of OSA is also reported in hypothyroid cases. (Misiolek M and 2007, Georgalas, 2011) The overlap between the two disorders may create a problem for the treating physician in differentiating both disorders and may result in a misdiagnosis or under-recognition of one of the disorders. Therefore, it is essential to consider both diseases in high risk patients and initiate the proper therapeutic plan accordingly. This chapter discusses how hypothyroidism interferes with respiratory physiology and then discusses the relationship between hypothyroidism and sleep disordered breathing.

2. Obstructive Sleep Apnea (OSA)

OSA is a disease characterized by repeated partial (hypopnea) or complete (apnea) collapse of the upper airway while asleep accompanied by surges in the sympathetic activity, cortical
arousals and episodes of hypoxia. (Chan et al., 2010) Patients usually present with complaints of excessive daytime sleepiness, un-refreshing sleep, fatigue or insomnia. Patients might have nocturnal awakening with breathing pauses or during patient’s sleep. The main risk factors for OSA are obesity, older age, family history, increasing neck circumference and male gender. (BaHammam et al., 2008, Tsara et al., 2010) Menopause is the main risk factor for women even after adjustment for age and body mass index (BMI). (Ancoli-Israel et al., 1989, Block et al., 1980) Other predisposing factors include craniofacial features, maxillomandibular malformation or adenotonsillar enlargements. (Johns et al., 1998, Moser and Rajagopal, 1987, Orr and Martin, 1981) The prevalence of OSA syndrome (AHI> 5/hour and excessive daytime sleepiness) is estimated to be 2% to 4% of adults. (Young et al., 2002, Punjabi, 2008) Epidemiologic data suggest that roughly 1 of every 5 adults has at least mild OSA and 1 of every 15 adults has at least moderate OSA. (Young et al., 2002) The National Sleep Foundation survey found that 26% of the population has a high probability of OSA. (Hiestand et al., 2006) It is always essential to identify and treat persons with OSA because of its strong association with several medical conditions, occupational and social consequences. Untreated OSA can result in increased risk of cardiovascular morbidities such as myocardial infarction, congestive heart failure, stroke, refractory hypertension, and cardiac arrhythmia. (Guilleminault et al., 1983, Logan and Bradley, 2010, Somers et al., 2008, Ehrmann et al., 2011) Furthermore, cognitive dysfunction, depression, impaired glucose tolerance, occupational and increased motor vehicle accidents are the other consequences. (Sateia, 2003, Kaplan, 1992, Horne and Reyner, 1999, Radun and Summala, 2004) Treatment with continuous positive airway pressure (CPAP) can help in restoring the airway and reversing the majority of the associated morbidities. (Jean-Louis et al., 2010, Ferini-Strambi et al., 2003)

3. Hypothyroidism and the respiratory system

Respiratory system components (respiratory center, upper airway and lower respiratory system) can be affected by deficiencies in body hormones as well as excess hormonal secretion. (Saarresanta and Polo, 2002, Saarresanta and Polo, 2003, Behan et al., 2003, Takasaki and Hayashi, 1985) Thyroid hormone is one of the major body hormones. Its deficiency has been associated with multiple cardiovascular complications, respiratory failure and coma. (McQuade et al., 2011, Takamura et al., 2010, Behnia et al., 2000, Hall and Scanlon, 1979) The involvement of the respiratory system has resulted in a spectrum of clinical disorders including SBD, pulmonary hypertension, hypoventilation and severe respiratory failure. The following section explains the mechanisms through which hypothyroidism affect the respiratory system.

Ventilatory drive

Hypothyroidism is associated with diminished ventilatory drive for both hypoxia and hypercapnia. In animal models of induced hypothyroidism, a decrease in peripheral chemoreceptor response to hypoxia and hypercapnia has been observed. (Simsek et al., 2004) In humans, approximately, one third of the hypothyroid patients have a blunted
ventilatory response to hypoxia/hypercapnia. (Zwillich et al., 1975, Duranti et al., 1993, Massumi RA, 1964) Predictors of blunted ventilatory response in hypothyroidism have been identified as female gender and very high levels of thyrotropin (>90 mIU/l). (Ladenson et al., 1988) It is the severe form of hypothyroidism that is associated with diminished ventilatory control. Cases of myxedema and severe hypothyroidism (thyroid ablation) were found to have a diminished hypoxic ventilatory drive that was reversible with hormonal replacement therapy. (Zwillich et al., 1975) However, diminished hypercapnic ventilator drive was only seen in myxedema cases and was not responsive to hormonal therapy. (Zwillich et al., 1975) In a case report of a patient with hypothyroidism, central sleep apnea with blunted ventilatory response to hypoxia but normal hypercapnic ventilatory response, treatment with thyroxine therapy have resolved the central apneas and restored the hypoxic drive. The normal hypercapnic ventilatory drive has doubled with thyroxine therapy. (Millman et al., 1983) Hypoxic ventilatory drive has a rapid response to thyroxine replacement than hypercapnic ventilator drive. It might be that the central chemoreceptors require longer duration of therapy or they sustain a long-term impairment. The use of intravenous thyroxine therapy was shown to improve both hypoxic and hypercapnic ventilatory drive within one week of therapy. (Duranti et al., 1993) Severe degrees of alveolar hypoventilation and coma have also been reported in cases of severe hypothyroidism (myxedema). (Behnia et al., 2000, Orr et al., 1981, Wall, 2000, Jordan, 1995)

Hypothyroidism is reported in 3% of difficult to wean mechanically ventilated patients. (Datta and Scalise, 2004) Despite this low rate, it is a potentially treatable cause and should be considered when evaluating patients who fail to wean. Successful weaning from ventilator following correction of hypothyroidism has been reported. (Pandya et al., 1989) Difficulty in weaning can be multifactorial in hypothyroid patients due to the multiple effects exerted by the hormone deficiency on different levels of the respiratory system.

**Upper respiratory tract**

- **Mechanical Obstruction:** Enlargement of the thyroid gland (goiter) in the presence of hypothyroidism or euthyroid state can create a mass effect on the upper airway,(Deegan PC, 1997, De Felice et al., 2006, Eloy et al., 2007) particularly when resuming the supine position. Such mechanical obstruction becomes prominent and can be associated with severe apneas. (Teramoto et al., 1995) Progressive enlargement of the thyroid goiter can further lead to stridor and an emergency intervention might be required in such severe cases. (Deegan PC, 1997) Reports have showed improvement of OSA with thyroidectomy. (Agrama, 2011)

- **Soft Tissue Infiltration:** As a part of the generalized skin and soft tissue infiltration in hypothyroidism, the upper airway and particularly the pharynx gets narrowed. In hypothyroidism, mucopolysaccharides and proteins infiltrate the skin causing skin thickening, infiltrate the tongue causing enlargement and infiltrate the neck soft tissue resulting in variable degrees of upper airway obstruction. (Devdhar et al., 2007, Batniji RK, 2006, Watson and Pearce, 1949) Hypothyroidism also alters the myosin heavy chain profile specifically in the main dilator muscle the genioglossus muscle, which
results in compromising the muscle function. (Petrof et al., 1992) Despite these changes in upper airway structure and function, hypothyroidism per se is not an independent risk factor for OSA if other known risk factors as male gender and obesity are not present. (Pelttari et al., 1994) Upper airway obstruction in hypothyroid patients might not be very evident initially. During stressful situations, occult hypothyroidism can result in devastating outcomes such as in post-extubation upper airway obstruction following emergency intubation or post-operatively. Cases of severe emergency obstruction in undiagnosed hypothyroidism have been reported. (Sherry and Hutchinson, 1984, Stahl N, 1988)

**Lower respiratory tract**

As with upper respiratory tract, the different structures of the lower respiratory tract can be affected to a variable degree with alterations in thyroid hormone levels.

- **Airways:** Very few studies have investigated airway diseases in hypothyroidism. In one study, patients with treated hypothyroidism were found to have more symptoms of breathlessness and wheeze. (Birring et al., 2003) And when evaluated by Methacholine challenge test, patients with treated hypothyroidism had more airways hyperreactivity than normal healthy individuals. Induced sputum showed higher levels of inflammatory cells, absolute neutrophil count, absolute lymphocyte count and increased levels of sputum interleukin-8 suggesting increased airway inflammation compared to control. (Birring et al., 2005)

- **The lung parenchyma:** The interstitium can also be affected in hypothyroidism; two cases of lung fibrosis have been reported in patients with severe hypothyroidism. Initiating therapy for hypothyroidism was associated with significant clinical and radiological improvement in lung fibrosis. (George et al., 2009)

- **Respiratory Muscles:** Both inspiratory and expiratory respiratory muscles are weakened in hypothyroidism in a direct linear relationship to the thyroid hormone level and it is reversible with thyroxine therapy. (Siafakas et al., 1992) Furthermore, thyroid deficient muscles have impaired free fatty acid utilization, which enhances their glycogen consumption, thereby reducing skeletal muscle endurance. (Baldwin et al., 1980) One of the major inspiratory muscles that are involved in hypothyroidism is the diaphragm. Diaphragm weakness can be very severe and associated with hypoventilation. (Martinez et al., 1989, Laroche et al., 1988)

- **Pulmonary Vasculature:** Both hyper/hypothyroidism has been associated with pulmonary arterial hypertension (PAH). (Li et al., 2007, Arroliga et al., 2000) A prevalence of 22-24% of hypothyroidism is reported in patients with PAH. (Curnock et al., 1999, Silva et al., 2009) It is thought that hypoxia/hypercapnia in hypothyroid patients is responsible for causing and worsening PAH. It is also known that both disorders are associated with autoimmune diseases, which raises the possibility of an immune pathophysiological mechanism. (Badesch et al., 1993, Chu et al., 2002)

### 4. Prevalence studies of hypothyroidism in OSA

The first case reporting an apneic episode in a patient with myxedema was published in 1964. (Massumi RA, 1964) Following that, studies have investigated further the prevalence
of OSA in hypothyroidism population and vice versa (Table 1). Overall, the prevalence of clinical hypothyroidism in patients diagnosed with OSA or referred to sleep centers with a clinical suspicion of OSA is not higher than the prevalence in the general population. The prevalence in patients evaluated by polysomnography for OSA is 0.7-3.4%, depending on the upper limit set for normal TSH, gender and age distribution of the studied samples. (Lin CC, 1992, Meslier et al., 1992, Winkelman JW, 1996, Kapur VK and BM, 1998, Winkelman et al., 1996) Kapur et al, reported a prevalence of 1.4% of subclinical hypothyroidism in OSA patients and this association was greater in females and those less than 50 years of age. (Kapur VK and BM, 1998) In a group of Taiwanese patients with OSA, a prevalence of 3.1% was reported despite using higher TSH level (>25 mIU/l) to define hypothyroidism. (Lin et al., 1992) The prevalence is also not significantly different in patients highly suspected to have OSA (1.5%) than those already diagnosed to have OSA by overnight sleep study (2.4%). (Skjodt et al., 1999) This is similar to Winkelman and co-workers who reported a prevalence of 1.6% in patients suspected to have OSA and 2.9% in those confirmed to have OSA. (Winkelman et al., 1996) Other studies have reported a much higher prevalence. In a study of 78 overweight and obese adult patients referred to a sleep clinic, a prevalence rate of 11.5% was reported. (Resta O, 2004) The studied population was characterized by higher BMI, older age and more females. All these three variables are known risk factors for hypothyroidism, which might have resulted in a higher rate. (Sawin CT, 1979, Bilous and Tunbridge, 1988, Fox et al., 2008) Females with OSA have been reported to have higher rates of undiagnosed and diagnosed hypothyroidism. (Winkelman et al., 1996, Alotair and Bahammam, 2008) In clinical practice, these variables are important to consider when assessing the risk of hypothyroidism in patients with suspected or diagnosed OSA. Female gender, increased BMI and older age are also well established risk factors for hypothyroidism. (Sawin CT, 1979) This might explain the higher prevalence of hypothyroidism reported in some studies. (Resta O, 2004) Nevertheless, increased age and BMI are the main risk factors for OSA. (Punjab, 2008, Hiestand et al., 2006) Thus, the co-existence of both diseases is expected and a high index of suspension is required in high risk patients.

Some of the previous studies defined hypothyroidism as the presence of a high serum thyroid-stimulating hormone (TSH) level without commenting on thyroxine hormone level. This means that some of the patients thought to have hypothyroidism may actually have had subclinical hypothyroidism, which carries different therapeutic and prognostic implications (Miller and Husain, 2003, Winkelman et al., 1996, Pham and Shaughnessy, 2008). In a recent study, Bahammam et al. reported the prevalence of newly diagnosed clinical hypothyroidism as 0.4%, and the prevalence of newly diagnosed subclinical hypothyroidism as 11.1%. (Bahammam et al., 2011) In the non-OSA patients, the prevalence of newly diagnosed clinical hypothyroidism was reported as 1.4%, and the prevalence of newly diagnosed subclinical hypothyroidism as 4%. (Bahammam et al., 2011) The authors concluded that the prevalence of newly diagnosed clinical hypothyroidism was low; however, subclinical hypothyroidism was common among patients with OSA. In lieu of the uncertainty of the benefit achieved by treating subclinical hypothyroidism, the authors recommended not to perform routine thyroid function testing for OSA patients. (Bahammam et al., 2011)

5. Prevalence studies of OSA in hypothyroidism

Limited data are available about the prevalence of OSA in hypothyroid patients (Table 2). The incidence is estimated to range from 25-82%. Most of the obtained data are from case reports and case series and their findings are variable. In a study of 50 patients with primary hypothyroidism, 30% where found to have OSA (AHI ≥5/hour). (Jha et al., 2006) These patients had overt severe hypothyroidism as manifested by TSH levels and symptoms. For milder cases and subclinical cases, the prevalence might be less. The variability in the results is influenced by the characteristics of the studied group. Predominance of male gender can result in a higher prevalence of OSA as it is one of the main risk factors for OSA. In smaller studies, a higher prevalence has been reported. (Rajagopal et al., 1984)

Table 2. Prevalence Studies of OSA in Hypothyroidism

6. The clinical effects of treating hypothyroidism in OSA patients

Theoretically, replacing thyroid hormone should reverse most if not all the complications associated with the state of deficiency. However, in real clinical practice, this is not absolutely correct. Changes such as respiratory muscle weakness can be reversible with thyroxine therapy. Difficult weaning in hypothyroid patients can be facilitated with thyroxine therapy too and mechanical obstruction due to thyroid goiter can be reverted with thyroidectomy. However, OSA response to thyroxine therapy is variable. In a case series of 10 hypothyroid patients with OSA, treatment with thyroxine was associated with nocturnal
angina and arrhythmia in two patients. Initiation of CPAP therapy prevented angina and arrhythmia. Eight of these patients were followed after achieving euthyroid state and six of them had persistent sleep apnea requiring CPAP therapy. (Grunstein and Sullivan, 1988) Thereby, treatment of hypothyroidism in the presence of OSA can be potentially hazardous and lead to cardiovascular complications even with small doses of thyroxine as thyroxine therapy may increase metabolic rate in the presence of significant hypoxia. Combination therapy (CPAP + Thyroxine) can be helpful in such situation. In another series of nine hypothyroid patients with OSA (AH1 range 17-176/hour), thyroxine therapy improved outcome. Six of them were obese and had the higher range of AH1 and showed significant improvement in AH1 after 3-12 months of thyroxine therapy despite no improvement in weight. (Rajagopal et al., 1984) Another series of 5 patients with OSA who received thyroxine therapy showed significant reduction in AH1 after 4 months of therapy; however, snoring persisted and required longer duration of therapy to improve. (Lin et al., 1992) Snoring refers to upper airway resistance and the longer duration required to improve it is basically related to the duration needed to resolve or improve upper airway changes induced by hypothyroidism. In a larger group of patients, Resta and co-workers divided patients into 3 groups: group A: 63 patients with normal thyroid function, group B: 30 patients affected with subclinical hypothyroidism and treated with levothyroxine for at least 2 years and group C: 15 patients with TSH >4mIU/l and not treated with levothyroxine. (Resta et al., 2005) The prevalence and severity of OSA did not differ between the three groups and levothyroxine therapy did not influence OSA outcome in patients with subclinical hypothyroidism. It was also noticed that levothyroxine therapy in patients with subclinical hypothyroidism and OSA was associated with less daytime sleepiness as measured by the Epworth sleepiness scale when compared to the untreated group. (Resta et al., 2005) Untreated subclinical hypothyroidism by itself is a known cause of excessive daytime sleepiness measured both subjectively and objectively, which improved with thyroxine therapy. (Shinno et al., 2009) On the other hand, the outcome of treating primary hypothyroidism with levothyroxine in patients with OSA has resulted in a significant improvement in AH1 within 7-11 months of therapy. This improvement was accompanied by significant reduction in BMI, skinfold thickness, pedal edema and other biochemical markers. (Jha et al., 2006) However, in the same study, two patients have lost follow-up and both failed to show any improvement in OSA following levothyroxine therapy. One is thought to be due to his overweight that did not reduce with therapy. (Jha et al., 2006) Failure to improve OSA by achieving euthyroid state suggests that hypothyroidism is not the only factor and other factors play a role in causing OSA. It is also thought that thyroid hormone deficiency results in long term changes in the upper airway and thus improvement in OSA lags behind achieving the euthyroid state. (Grunstein et al., 1993) Furthermore, it is the treatment of the severe forms of hypothyroidism (myxedema) that improves the concomitant OSA. (Orr et al., 1981) Based on the available evidence, thyroxine cannot be considered as the only therapeutic option for OSA in patients with hypothyroidism especially in elderlies and those with cardiovascular diseases. (Veasey et al., 2006) The degree of hypoxia accompanying apneas may worsen with initiation of thyroxine therapy. In the hypothyroid state and as a result of the low metabolic rate, oxygen consumption by several body organs is less than usual, which can help to maintain a reasonable oxygen level compared to the duration and severity of apneas. With the increment in basal metabolic rate.
seen with the commencement of thyroxine therapy, oxygen consumption is increased by body organs and short-duration apneas/hypopneas can result in dramatic oxygen desaturation. Therefore, CPAP therapy should not be delayed for months awaiting the results of thyroxine use. The lack of response to thyroxine suggests that either there is no casual association between hypothyroidism and OSA or those alterations in breathing mechanics and upper airways require longer duration of therapy to reverse them and that longer duration of follow up might show a beneficial effect of thyroxine therapy.

Table 3. Summary of outcome studies of thyroxine therapy in OSA patients

7. Evaluating thyroid function in OSA patients

It is important when ordering a laboratory investigation for any disease to consider the prevalence of the problem, the associated complications, cost-effectiveness and the effectiveness of treating the disease. Blood tests TSH, thyroxine (T4) are not clinically indicated in patients with OSA. Hypothyroidism can be associated with severe cases of OSA +/- hypoventilation but it is not an independent risk factor. Nocturnal upper airway obstruction has been evaluated in both hypothyroid and euthyroid subjects. The incidence of upper airway obstruction is higher in hypothyroid 7.7% compared to euthyroid 1.5% but after controlling for weight, age and gender, hypothyroidism does not significantly
predict upper airway obstruction. (Pelttari et al., 1994) Thus, upper airway obstruction is related to obesity and male gender and not to hypothyroidism per se. The prevalence of clinical hypothyroidism, as mentioned above, is not higher than the general population. Furthermore, there is no strong evidence to support the resolution of OSA with thyroxine therapy. However, thyroxine therapy should be initiated in hypothyroid patients to manage the other co-morbidities associated with hypothyroidism but not as a medical therapy for OSA. Thyroxine therapy can not abandon the need for CPAP therapy and should not delay its initiation. The recommended practice is to be selective when ordering TSH/T4 test to high risk population (females, morbidly obese and older age), persistent symptoms of fatigue and sleepiness despite proper CPAP therapy and in those with secondary causes for hypothyroidism (thyroid ablation, thyroidectomy, panhypopituitarism).

8. Conclusion

For OSA patients, the prevalence of clinical hypothyroidism is not higher than the general population. It is essential to consider the risk factors for hypothyroidism when evaluating patients for sleep apnea as well as considering OSA risk factors when evaluating hypothyroid cases. Routine blood testing for TSH and T4 should be saved for OSA patients with severe obesity, persistent sleepiness despite adequate CPAP therapy and with overt hypothyroid symptoms and signs. For hypothyroid patients with symptoms suggestive of OSA, a diagnostic sleep study is warranted and CPAP therapy should be commenced prior to thyroxine therapy especially in the elderly and patients with cardiovascular diseases. Re-evaluating OSA patients after achieving euthyroid state can be done, especially if accompanied by weight reduction. Some of OSA cases might resolve but the majority seems to persist. Long-term studies might be able to explore better the impact of thyroxine therapy and help in understanding time-course of the problem.

Hypothyroidism and Obstructive Sleep Apnea

Winkelman Jw, G. H., Piscatelli N, Lukas Se, Dorsey Cm, Cunningham S 1996. Are thyroid function tests necessary in patients with suspected sleep apnea? *Sleep*, 19, 790-793.

Hypothyroidism is the most common thyroid disorder and it is significantly more frequent than presented - millions of people suffer from this disease without knowing it. People with this condition will have symptoms associated with slow metabolism. Estimates of subclinical hypothyroidism range between 3 to 8 %, increasing with age, whereas it more likely affects women than men. About 10% of women may have some degree of thyroid hormone deficiency. Hypothyroidism may affect lipid metabolism, neurological diseases or other clinical conditions. The book includes studies on advancements in diagnosis, regulation and replacement therapy, thyroid ultrasonography and radioiodine therapy for hypothyroidism. “Hypothyroidism - Influences and Treatments” contains many important specifications, results of scientific studies and innovations for endocrine practice.
