Chapter 17

Saphenous Vein Graft Aneurysms

G. Kang and K. Kang

Additional information is available at the end of the chapter

http://dx.doi.org/10.5772/46035

1. Introduction

Saphenous Vein Grafts were introduced to the technique of coronary artery bypass surgery for the treatment of severe coronary artery stenoses more than 40 years ago (1,2). Saphenous vein graft aneurysm defined as abnormal dilation of the bypassed vein graft remains a rare complication but increases the risk of morbidity and mortality (3,4). Vein graft aneurysms are associated with extensive plaque and atherosclerotic debris and can lead to angina and myocardial infarction both with graft occlusion and distal embolization (3,4,5). Saphenous vein aneurysms can rupture with devastating effects leading to shock or fistula formation and also cause compression of surrounding structures. This can lead to enlarged mediastinum (4), atrial fistulas (3), pulmonary leakage with hemoptysis (3), and repeat coronary artery bypass grafting (4). In my practice, I have reported, a leaking saphenous vein graft aneurysm large enough to compress the right heart chambers causing tamponade physiology (4).

2. Definition and epidemiology

The aneurysms are uncommon, are usually, 1 cm to 14 cm in size and taking the rarity of reporting into account, the aneurysms are seen in less than 1% of coronary bypass patients on follow up (5). Aneurysms are seen at an average age of 59 years and more often in men (5). Saphenous vein graft aneurysms, like the aneurysms elsewhere are defined as vessel dilations of 1.5 times the size of the reference vessel and were first described 7 years after the first Coronary Bypass surgery in 1975 (6).

2.1. Pathophysiology

An aneurysm may be true aneurysm where all the three vessel layers are involved or false where the endothelium or even the media may be disrupted leading to an intramural hematoma or hemorrhage (5). The most common etiology is atherosclerosis but other causes include formation of true or false aneurysms post angioplasty, true aneurysm formation at
the site of a venous valve or false aneurysms at the site of suture rupture or false aneurysm from infectious etiology (5). Aneurysms may result from chronic steroid use or unsuspected harvesting of varicose veins (5).

The true aneurysms are fusiform and often in the middle of the graft and the false aneurysms are saccular and often at the origin of the graft but the aneurysms can be seen anywhere (4,5). Inflammatory causes as in aneurysms elsewhere may also be considered but lack any specific anti-inflammatory therapy (7).

2.1.1. Symptoms

True aneurysms are often asymptomatic in about half of the patients that present to medical attention and are discovered incidentally on imaging studies (5). They are seen most often in left anterior descending artery venous bypasses followed by right coronary and circumflex artery bypasses, respectively.

A triad of chest pain, mediastinal enlargement and previous coronary bypass may raise suspicion of a saphenous vein graft aneurysm (4). The symptoms at presentation are usually angina, myocardial infarction, congestive heart failure or variety of symptoms from graft occlusion, embolization, fistula formation or compression of surrounding structures (4,5). False aneurysms are usually symptomatic, however. Only minority of patients with false aneurysms is asymptomatic and the majority of the patients with false aneurysm present with the same symptoms as true aneurysms but the incidence of rupture is higher than with true aneurysms (5). Rupture of the aneurysm into the lung may lead to hemoptysis and into a cardiac chamber can lead to a fistula (8,9,10). Also, compression of left internal mammary artery graft by an aneurysm was recently described (9).

Figure 3. Intravascular ultrasound showing pseudoaneurysm at the 2O'clock position with disrupted endothelium
Figure 4. True aneurysm from 4 to 6O’clock position on intravascular ultrasound
Figure 5. Chest CT scan image of a large leaking aneurysm compressing the right atrium
3. Signs

A variety of signs related to the pathophysiology at the time of presentation may be seen. A pulsatile mass on palpation or ischemia causing a gallop rhythm may be noted. If the rupture of the aneurysm occurs then murmurs related to fistula formation or shock secondary to bleeding or compression may be evident (4,5,8,9,10).

4. Workup

EKG may show ischemia, infarction or tamponade depending on presentation (4). CXRay may show mediastinal enlargement or pleural effusion (4). Diagnostic test of choice is often coronary angiography that is the gold standard before therapeutic decision-making (5). CT or MRI scanning can also accurately define the extent and size of the aneurysm and the associated complications (4). Echocardiography may show a mass as well (4).

5. Conclusion

The average time to diagnosis is 10-20 years post CABG (5) and over that time period, systemic pressures in veins and atherosclerotic disease progression is the most likely cause of aneurysm formation. Medical treatment for atherosclerotic disease is, hence, recommended as primary treatment (4,11). Antiplatelet, cholesterol lowering and anti-hypertensive drugs are standard of care in the treatment (4,11).

The surgical treatment is recommended for large aneurysms but is still controversial as to the size where surgery is necessary (4,11,12). The graft diameter of more than 2 cm is arbitrarily, an indication for surgery (4,5). But, thicker aneurysmal wall or excellent flow through a graft may sway towards medical therapy in borderline cases. Pseudoaneurysms are often treated surgically and distinguished by the narrow neck and ultrasound findings of a disrupted vein graft wall (4,5).

Surgery may involve ligating the aneurysmal graft (4,12,13) and placing a new graft for revascularization (most commonly). Percutaneous techniques are experimental and may include investigational use of stenting and coil embolization or placement of Amplatzer vascular plugs (14). Additionally, covered Jomed stents (Abbott) or even multiple regular stents with prolonged balloon inflation have been tried (15). Other covered stents like Arium iCAST have been tried in our catheterization laboratory. (4,15). In my practice, I have injected platinum coils with expandable hydrogel polymer directly into the pseudoaneurysms with narrow neck or through stent struts for aneurysms with wide neck.
