Chapter 9

Explore Laser Acupuncture’s Role

Wen-Long Hu, Yu-Chiang Hung and I-Ling Hung

Additional information is available at the end of the chapter

http://dx.doi.org/10.5772/55092

1. Introduction

Acupuncture has been widely used in the treatment of many diseases for over 2000 years. It is traditionally performed by inserting thin needles into acupuncture points in the human body; this is known to affect the functions of various organs. According to the theory of traditional Chinese medicine, energy (or Qi) flows through the body along specific paths known as meridians. Any disturbance in this Qi results in an energy imbalance in the body; this imbalance may in turn result in disease. Acupuncture attempts to regulate and restore energy balance by stimulating specific acupoints along the meridians and thereby treat the underlying disease. In 1979, the World Health Organization (WHO) identified 43 conditions that might benefit from acupuncture. In 1996, WHO confirmed 64 indications for acupuncture treatment.

Recently, laser acupuncture (LA) has been used as a complementary and alternative therapy in addition to traditional acupuncture. It was first introduced clinically in the 1970s [1, 2]. LA is defined as the stimulation of traditional acupuncture points with low-intensity, non-thermal laser irradiation [3]. A laser beam is an electromagnetic wave and can stimulate the acupuncture points in the human body by depositing energy without heating. In doing so, the beam excites the channels and properties, regulates the function of organs, and promotes metabolism. It can function as both acupuncture and moxibustion via different frequencies, e.g., the information of the needle type (steel, gold/silver, left/right turn etc.). According to the research of Manfred Reininger et al, frequencies (Reininger frequencies: LU= 824 Hz, LI= 553 Hz, ST= 471 Hz, SP= 702 Hz, HT= 497 Hz, SI= 791 Hz, BL= 667 Hz, PC= 530 Hz, TE= 732 Hz, GB= 583, LR= 442 Hz; Bahr frequencies: B1= 599.5 Hz, B2= 1199 Hz, B3= 2388 Hz, B4= 4776 Hz, B5= 9552 Hz, B6= 19104 Hz, B7= 38208 Hz; Nogier frequencies: A’= 292 Hz, B’= 584 Hz, C’= 1168 Hz, D’= 2336 Hz, E’= 4672 Hz, F’= 9344 Hz, G’= 18688 Hz) can be applied to acupuncture points to improve the meridian energy. In this chapter, we explore laser acupuncture’s role in modern medicine with a focus on how it strengthens and promotes the current methods of treatment.

2. Laser acupuncture vs. acupuncture

Instead of using a metal acupuncture needle, LA uses red or near-infrared light with a wavelength between 600 and 1000 nm and power between 5 and 500 mW. It is also referred to as low level laser therapy (LLLT), with 0.1–0.5 J/cm² being deposited per acupoint, or 1–4 J/cm² per Ashi point. Because of the low absorption of laser light by human skin in the given wavelength range, it has been hypothesized that laser light can penetrate deeply into the tissue, where it may have a photobiostimulation effect [4].

LA combines the advantages of traditional Chinese acupuncture and modern laser medicine. However, in some ways, laser energy may be more suitable than the traditional needle for stimulating the oscillating energy field of the meridian system. The correct frequency modulation of the monochromatic laser beam energizes the meridian and acupuncture point and thereby improves the oscillation of the meridian’s own frequency. In addition, some patients may avoid acupuncture because of fear of pain and LA may be less invasive, less painful, and safer than traditional acupuncture. It may also be an improvement over traditional moxibustion, because it uses similar energy levels but avoids harmful effects related to smoke and heat (Table 1).

3. Review of the clinical literature

3.1. Pain

Assessment of the methods and findings of clinical trials on LA is confounded by the lack of detail in some studies in the literature. It is also noteworthy that all studies reporting negative results (no significant benefit of LA compared with control or sham conditions) lacked details regarding treatment parameters, such as laser power or dose [5].

Table 1. Comparison of traditional and laser acupuncture
3.1.1. Low back pain

Glazov used multiple regression analysis to identify which baseline characteristics predicted pain changes in the immediate, short, and intermediate terms. They found that higher pain scores at baseline predicted greater pain relief after LA for chronic non-specific low back pain. Adjusted analysis suggested a clinically significant effect on pain with LA compared to sham treatment ($P < 0.05$), at short term follow-up only [6]. Later, Glazov et al. performed a randomized controlled trial comparing the effects of laser acupuncture (LA) and sham laser treatment in reducing pain and disability in adults with chronic non-specific low back pain. Their results showed no effect of LA in reducing pain using infrared light at 0.2 J/point [7]. A possible reason for this result is dose dependency issue [8].

On the other hand, Fiore et al. [9] examined the short-term effects of high-intensity laser therapy versus ultrasound therapy for the treatment of low back pain in a randomized controlled trial without placebo control group. At the end of a 3-week intervention period with 5 treatments per week, participants in the laser therapy group showed a significantly greater decrease in pain and an improvement in related disability compared with the ultrasound group. This study suggests that laser therapy is a promising treatment option for the rehabilitation of low back pain.

3.1.2. Myofascial pain

LA has been used to treat myofascial pain in the masticatory musculature and trapezius muscles. Some trials focusing on the ability of LA to relieve myofascial pain found negative or contradictory results, which may reflect the poor methodologies used before 2001 [10]. In recent years, randomized controlled trials revealed significant decreases in pain during both rest and activity, and an increase in pain threshold in patients treated with LA compared to those treated with needle-acupuncture and placebo, respectively. Although no definite conclusions can be drawn due to the low number of participants ($n = 11$), LA may be a good treatment option for patients wanting a noninvasive, complementary therapy [11]. LA appears to be an effective form of acupuncture for the management of these conditions [12].

3.1.3. Temporomandibular dysfunction

The effectiveness of LLLT for the control of pain in patients with temporomandibular disorder (TMD) has been evaluated in studies with various research designs. In one study, LA was applied to acupuncture points in TMD patients, and the results showed significant pain reduction and improvement in the electromyographic behavior of masseter muscles in maximal habitual occlusion after treatment, but no significant improvement was observed in mandibular movement. This shows that LA may have an effect for controlling pain in TMD patients [13, 14].
3.1.4. Lateral epicondylitis

LLLT is a conservative treatment for lateral epicondylitis (LE). A recent systemic review evaluated therapeutic effects of LLLT in treating LE in terms of pain, grip strength, range of motion (ROM), and weight tests. The results revealed that applying LLLT on myofascial trigger points is an effective means for pain reduction and also led to increases in grip force, ROM, and weight test [15]. However, most of the reviewed studies, which were all several decades old, showed no significant differences between the laser treatment and the placebo groups [16]. This may be related to dose or wavelength effects. LLLT at optimal doses of 0.5–7.2 J at 904 nm and possibly 632 nm administered directly to the lateral elbow tendon insertions, has been shown to offer short-term pain relief and reduce LE disability. No serious side effects were reported in that study. This finding contradicts the conclusions of the previously mentioned review [16], which failed to assess treatment procedure, wavelength, or optimal dose [17].

3.1.5. Knee osteoarthritis

Laser acupuncture has been widely used in treating knee osteoarthritis. A study by the Western Ontario and McMaster Universities (WOMAC) found a significant decrease in pain score in knee osteoarthritis patients treated with LA compared sham treatment [18]. Yurtkuran et al. used a range of pain indices to investigate the effects and minimum effective dose of LA in treating this condition. Although they found some pain reduction in the placebo group, statistically significant reduction in knee circumference was observed only in the laser group. They concluded that LA was effective in reducing periarticular swelling. They also noticed different effects for different knee joint acupoints. The most common acupoints they used were Dubi (ST35) and Neixiyan (EX-LE 4) [19].

3.1.6. Headache

Several randomized controlled trials have found LA to be an effective treatment for headache, especially in children, including both migraine and chronic tension-type headaches [20, 21]. LA was shown to decrease headache intensity, duration of attacks, as well as number of headache days per month.

3.2. Other conditions

3.2.1. Obesity

LA has been reported to be effective in weight control. Wozniak (2003) compared the efficacy of a low-calorie diet with and without concurrent LA in reducing visceral obesity in postmenopausal women. They observed a significantly greater drop in body weight, body mass index, and waist-to-hip ratio with the combined treatment [22]. More recently, Hu et al. evaluated the therapeutic effects of LA in subjects with simple obesity using a non-restrictive diet protocol. Significant reductions in body weight and body mass index were seen after 4 weeks
of LA treatment. Moreover, patient compliance was high, since this is a comfortable and non-restrictive diet protocol [23].

3.2.2. Carpal tunnel syndrome

In patients with carpal tunnel syndrome (CTS), lower-level-laser therapy plus microamperes transcutaneous electric nerve stimulation (TENS) applied to acupuncture points has been shown to significantly reduce pain. In this study, both subjective (McGill Pain Questionnaire scores) and objective (sensory and motor latencies and Phalen and Tinel signs) measurements revealed that this combined approach was effective in treating CTS [24]. Branco examined the effects of various conservative treatments on CTS patients, including LA, TENS, needle acupuncture, and Chinese herbal medicine formulas, pain reductions were significantly greater with the LA compared to the other treatments, including some patients failed to have symptom relief after surgical release. Suggested mechanisms of pain reduction they proposed included increased adenosine triphosphate (ATP) at the cellular level, decreased inflammation, and temporarily increased serotonin level [25].

3.2.3. Postoperative vomiting

Postoperative nausea and vomiting (PONV) are frequent side effects of general anesthesia in children. In 1998, LA was shown to reduce PONV in children after strabismus surgery. In this study, laser stimulation of PC6 occurred 15 min before administration anesthesia and again 15 min after arriving in the recovery room. In the laser stimulation group, the incidence of vomiting was significantly lower (25%) than that in the placebo group (85%) [26]. In another study, Butkovic et al. compared the effectiveness of LA to that of metoclopramide in preventing PONV in children after sevoflurane anesthesia. There were no statistically significant differences between the LA and metoclopramide groups in occurrence or timing of vomiting (P < 0.001). They concluded that LA is equally as effective as metoclopramide in preventing PONV in children [27].

3.2.4. Smoking cessation

A prospective observational 2 year study showed that the Smokex-Pro method (Table 2) is an effective aid in smoking cessation. The treatment was well tolerated and showed only mild and temporary side effects. Additional advantages included lower cost and shorter treatment duration compared to other smoking cessation programs. However, controlled clinical trials are still needed to confirm the results of this study and to refine the treatment for maximum efficacy [28].

3.2.5. Alcohol addiction

Auricular acupuncture has been used in the treatment of alcohol addiction for many years. Zalewska-Kaszubska et al. performed a study aimed at intensifying this method by adding
laser biostimulation for treatment of patients with alcohol dependence syndrome. The patients received a single helium-neon laser neck biostimulation and 10 auricular acupuncture treatments with an argon laser. After 2 months of treatment, improvements in Beck Depression Inventory-Fast Screen (BDI-FS) scores and increases in beta-endorphin level were observed. These results suggest that laser therapy can be useful as an adjunct treatment for alcoholism [29].

3.2.6. Asthmatic children

It has been shown that LA significantly decreases mean weekly PFV as a measurement of bronchial hyper reactivity in asthmatic children. In this study there were no significant effects on FEV1, quality of life, or additional medication [30]. Another randomized control trial concluded that a single LA treatment offers no protection against exercise induced bronchoconstriction in pediatric and adolescent patients [31].

3.2.7. Neurogenic pruritus

Stellon described successful LA treatment in a 6-year-old girl with neurogenic pruritus of the abdomen, which was the first case report on LA treatment for this condition. The main advantage of using low energy laser light to stimulate points, as opposed to using acupuncture needles, was that it causes little or no sensation during the treatment which is particularly useful in pediatric population [32].

3.2.8. Depression

Depression is a major public health problem, and there is some evidence supporting the effectiveness of needle acupuncture in its treatment. Quah-Smith et al. investigated the effects of LA in treating depression patients and found that Depression Inventory scores decrease from baseline by 16.1 points in the intervention group and by only 6.8 points in the sham control group (P < 0.001). However, the beneficial effect was short-lived. The LA was well tolerated, with transient fatigue being the most common adverse effect [33]. Additional controlled clinical trials are needed to confirm the results of this study and to refine the treatment for maximum efficacy.

3.2.9. Nocturnal enuresis

LA therapy has been shown to be significantly more effective in reducing bed-wetting in primary monosymptomatic nocturnal enuresis patients compared to placebo treatment. In this study, they found no significant effects on maximal voided volume (first morning void excluded), maximal morning voided volume, voiding frequency, enuresis frequency before and after treatment, or nocturnal urine production after LA treatment. However, they did find significant increases in average daytime voided volume compared to the placebo group. They concluded LA was a safe but inefficient treatment for these patients [34]. However, a different study showed subtle effects on bladder reservoir function after LA
treatment [35]. In comparison with pharmacological therapy using desmopressin, another study showed no statistically significant differences in success rates between desmopressin therapy and LA. LA is an alternative, noninvasive, painless, cost-effective, and short-term therapy for children with primary nocturnal enuresis, normal bladder function, and high nighttime urine production [36].

3.2.10. Autonomic nervous activity of night shift workers

Many studies have demonstrated high levels of affective disorders in night-shift workers. Wu et al. examined the impact of LA on autonomic nervous system (ANS) and heart-rate variability (HRV) of such workers. Compared with a placebo group, the treatment group had a statistically significant improvement in high-frequency (HF) HRV, low-frequency (LF) HRV, and LF:HF HRV ratio. This suggests LA may increase vagal activity and suppression of cardiac sympathetic nerves and could be used to help patients who have circadian rhythm disorders [37].

3.2.11. Whiplash injuries

Following introduction of compulsory seat belt use in cars, whiplash injuries of the cervical spine have become commonplace. Current treatment approaches resolve symptoms within a short time in most cases, but a small proportion of patients still develop persistent health problems. Aigner et al. combined LA with cervical collar treatment and medication (paracetamol and chloromezanone) to treat whiplash patients. They did not observe significantly greater improvements in any outcome measure at any time for LA compared to the other treatment protocols [38].

3.2.12. Postural instability

It is well known that the risk of falling is high among elderly people. Bergamaschi compared the effectiveness of auriculopuncture, ultralow-power LA, and placebo treatment in improving postural control in an elderly population. Balance performance was measured on a force platform before and after treatment. Although the small sample size did not allow reliable statistical analysis, the observed balance improvements were remarkable, and some differences were observed between the two kinds of stimulation. They found that both LA and auriculopuncture reduced nociceptive interference, thus improving postural control [39].

3.2.13. Peripheral artery disease

Cardiovascular disease is the most common cause of death in humans. The use of acupuncture as a complementary and alternative treatment for cardiovascular disease has been suggested in both humans and animals. Possible advantages of using acupuncture are the low cost of treatment and the low risk of collateral damage when used in combination with other medical treatments. In 2010, a trial was performed to compare the effects of traditional acupuncture and LA on arterial pressure and peripheral circulation of the inferior limbs in patients with
circulatory deficiencies. The results showed that only those treated with LA exhibited a significant increase in systolic pressure in their lower limbs, with a resulting improvement in Revascularization Index. This suggests that different stimuli on acupuncture points generate different variations of peripheral resistance in the lower limbs [40].

3.2.14. Cerebral cortical and subcortical activations

As recent studies have demonstrated, acupuncture can elicit activity in specific areas of the brain. Siedentopf et al. investigated the cerebral effects of LA at both GB43 acupoints with functional magnetic resonance imaging. Their results showed that LA produced significant, predominantly ipsilateral, brain activation within the thalamus, nucleus subthalamicus, nucleus ruber, the brainstem, and the Brodmann areas 40 and 22. No significant brain activations were observed within the placebo group. The fact that the observed effects were primarily ipsilateral supports the assumption that LA is mediated by meridians, since they do not cross to the other side of the body [41].

4. Discussion and conclusions

LA is a non-invasive technique involving the stimulation of traditional acupoints with low-intensity, non-thermal laser irradiation. Its clinical application is widespread even though its mechanisms are not well understood. LLLT can decrease inflammation by reducing the levels of biochemical markers (prostaglandin E2, messenger ribonucleic acid cyclooxygenase-2, IL-1β, TNF-α), neutrophil influx, oxidative stress, edema, and hemorrhaging [42]. Analgesia induced by laser phototherapy is mediated by peripheral opioid receptors [43], however LA has both local and distant analgesic effects that may be mediated by different mechanisms.

LA combines the positive effects of traditional acupuncture with LLLT. Compared with needle-based methods for manipulating Qi, LA has the advantages of being non-invasive and aseptic. Moreover, it is painless and safe because no heat is generated during the procedure, and it is more effective in some medical condition and requires less time than needle-based acupuncture [23]. No side effects or complications resulting from LA have been reported in any study so far.

We have presented evidence supporting the use of LA in the treatment of various types of acute and chronic pain, postoperative nausea and vomiting, nocturnal enuresis, alcohol addiction, smoking cessation, obesity, and cerebral cortical activation (Table 2). Inappropriate selection of points and frequencies, insufficient energy and therapeutic sessions will lead to a failure in laser acupuncture therapy. Further studies are needed to better define optimal treatment parameters, including wavelength, dose, and intensity, and to maximize the physiological benefit and cost effectiveness of treatment (Figure 1). In conclusion, LA integrates traditional acupuncture with LLLT, and is effective in treating many conditions. In the hands of an experienced physician, LA can be an effective alternative treatment method in modern medicine.

Table 2. Summary table of clinical researches into laser acupuncture

Figure 1. Graph of the therapeutic effects of laser acupuncture divided into psychological (pink) and physiological (dark blue) effects. The latter is determined by the shown factors.
Author details

Wen-Long Hu¹²³⁴, Yu-Chiang Hung¹² and I-Ling Hung³

¹ Department of TCM, Kaohsiung Chang Gung Memorial Hospital, Taiwan
² Chang Gung University College of Medicine, Taiwan
³ Kaohsiung Medical University College of Medicine, Taiwan
⁴ Fooyin University College of Nursing, Taiwan
