Chapter 19

Economic Evaluation of Diagnosis Tuberculosis in Hospital Setting

Luciene C. Scherer

Additional information is available at the end of the chapter

http://dx.doi.org/10.5772/54479

1. Introduction

Tuberculosis (TB) is an ancient disease, but not a disease of the past. After disappearing from the world public health agenda in the 1960s and 1970s, TB returned in the early 1990s for several reasons, including the emergence of the HIV/AIDS pandemic and the increase in drug resistance. More than 100 years after the discovery of the tubercle bacillus by Robert Koch, what is the status of TB control worldwide? The evolution of global TB control policies, including DOTS (Directly Observed Therapy, Short course) and the Stop TB Strategy, and assess whether the challenges and obstacles faced by the public health community worldwide in developing and implementing this strategy can aid future action towards the elimination of TB. (Lienhardt, Glaziou et al. 2012) The report of the Commission on Macroeconomics and Health of the World Health Organization has emphasized that tuberculosis is the most common of the infectious diseases. Tuberculosis is one of the most important health problems in the world, causing 1.4 million deaths each year, in 2011. (WHO, 2010)

The most of TB cases (82%) was concentrated in 22 countries around the world. In the year of 2010, in Brazil were detected 81946 cases, with 5000 death (WHO, 2010).

In Rio Grande do Sul, a state in extreme south of Brazil, the incidence of TB in 2011 was 46.1 per 100,000, with 4947 new cases. Porto Alegre, capital of Rio Grande do Sul shows incidence of 116 in 2009. (Sul 2011; Brazil 2012)

Tuberculosis is the first cause of death in patients with AIDS in Brazil. Patients with co-infection HIV/TB have had in treatment of Tuberculosis probability of worst outcome. Rio Grande do Sul, has had the major incidence of TB/HIV co-infection. The co-infection adversely affects the lives of individuals in both the biological and psychosocial aspects. (Neves, Canini et al. 2012)
Some factors can be considered as risk factors for co-infection of TB and HIV, as the impoverishment of the population, use of injecting drugs, the disruption of services on the epidemiology of TB control, the delay in the diagnosis of TB and increased risk of acquiring multi-drug resistant TB (MDRTB), essentially associated to the expansion of the disease in the world. (Kritski, Lapa e Silva et al. 1998). Multidrug-resistant tuberculosis (MDR-TB) is a major clinical challenge, particularly in patients with human immunodeficiency virus (HIV) co-infection. (Nathanson, Nunn et al.; Farley, Ram et al. 2011; Arjomandzadegan, Titov et al. 2012; Jain, Dixit et al. 2012; Udwadia 2012).

For the above, in recent years became consensus that the epidemic of TB in developing countries demands the evaluation of broader approaches, described in the Plan STOP-TB/OMS control global TB 2006-2015.

Among them have been prioritizing the implementation of:

a) improvements in access to diagnostic system user health; b) culture for mycobacteria in every patient suspected of TB and HIV positive and all TB patients in retreatment; c) sensitivity test for suspected cases of resistant TB (retreatment cases, treatment failure, contact MDR-TB or have been treated at the Health Unit with a high rate TB-MDR/XDR); d) review and economic evaluation under routine conditions of deployment of new technologies (phenotypic or molecular, automated or not) for the early diagnosis of TB, resistant TB patients with paucibacillary TB, HIV-infected or suspected drug-resistant TB.

Early detection of tuberculosis (TB) is essential for infection control. Rapid clinical diagnosis is more challenging in patients who have co-morbidities, such as Human Immunodeficiency Virus (HIV) infection. Direct microscopy has low sensitivity and culture takes 3 to 6 weeks (Sharma, Mohan et al. 2005; WHO 2006). Diagnostic testing for tuberculosis has remained unchanged for nearly a century, but newer technologies hold promise for a revolution in tuberculosis diagnostics. Tests such as the nucleic acid amplification assays commercial and in house technologies allow more rapid and accurate diagnosis of pulmonary and extrapulmonary tuberculosis. (Rodrigues Vde, Queiroz Mello et al. 2002; Sanchez, Rossetti et al. 2006; Scherer, Sperhacke et al. 2007; Scherer, Sperhacke et al. 2011; Hida, Hisada et al. 2012). Xpert MTB/RIF (Xpert) is actually a promising new rapid diagnostic technology for tuberculosis (TB) which has characteristics that suggests large-scale roll-out. (Vassall, van Kampen et al. 2011). In developing countries, in house Polymerase Rhain reaction (PCR) based on amplifying the IS6110 insertion element can be used for the amplification of Mycobacterium tuberculosis (MTB) DNA and offers the potential of a sensitive, specific and rapid diagnostic for ruling out or considering pulmonary tuberculosis (PTB) (Mehrotra, Metz et al. 2002; Sarmiento, Weigle et al. 2003; Schijman, Losso et al. 2004; Flores, Pai et al. 2005).

The appropriate and affordable use of any of these tests depends on the setting in which they are employed (Perkins 2000; Brodie and Schluger 2005). New tools for TB diagnosis, treatment and control are necessary, especially in health settings with a high prevalence of HIV/TB co-infection.

Although TB is one the greatest causes of mortality worldwide, its economic effects are not well known, especially in Brazil. Despite the fact that the families did not have to
pay for medications and treatment, given that this service is offered by the State, the
costs to families related to loss of income due to the disease were very high. The propor‐
tion of public service funds utilized for prevention is small. Greater investment in pre‐
vention campaigns not only might diminish the numbers of cases but also might lead to
earlier diagnosis, thus reducing the costs associated with hospitalization. The lack of an
integrated cost accounting system makes it impossible to visualize costs across the vari‐
ous sectors.(Costa, Santos et al. 2005)

To make rational decisions about the implementation of new tools in the medical routine,
cost-effectiveness studies are essential(Mitarai, Kurashima et al. 2001; Kivihya-Ndugga, van

A key step in cost-effectiveness analysis is to identify and value cost. The economic concept
of opportunity cost is central to cost-effectiveness analysis. When a public health agency
spends money to provide health care, this money is not available for housing, education,
highway construction, or as a reduction in income taxes. When a health care organization
spends money for bone transplantation, this money is not available for example for mam‐
nography outreach or something. When an elderly man spends time being vaccinated for
influenza, this time is not available to play golf or to work. An overall conceptual goal in
cost-effectiveness analysis is comprehensive identification of all costs of the intervention and
its alternative, including all of the opportunity costs.

Contributors to cost must be identified before the costs can be valued. The terms used to de‐
scribe the contributors to cost (e.g. direct costs, indirected costs, opportunity costs) are used
in different ways in different textbooks and in published cost-effectiveness analysis.

The definition of cost terms is the opportunity cost is the value of resources in an alter‐
native use, the direct cost is the value of all goods, services, and other resources con‐
sumed in the provision of an intervation or in dealing with the side effects or other
current and future consequence linked to it and the productivity costs are the costs asso‐
ciated with lost or impaired ability to work or engage in leisure activities and lost eco‐
monic productivity due to death attributable to the disease. These costs have been
substituted for indirect costs. There are several categories of direct costs. The first catego‐
ry of total direct cost is direct health cost, this category include costs with tests, drugs,
supplies, personnel, equipment, rent, depreciation, utilities, maintenance and support
services. The second category of total direct cost is direct non- health care cost, these cost
include for example the cost to patients to partake of the intervention e.g., transporta‐
tion, child care, parking). The third category of total direct cost is the cost of informal
caregiver time, this is the monetary value of the time of family members or volunteers
who provide home care. The fourth category of total direct cost is the cost of the use of patient time. Such studies provide insight into the composition of different
cost components, which may be the most important factor from the patient and the
health service’s perspectives. Recent studies have compared the cost effectiveness of
news tools for diagnosis, treatment and control in Tuberculosis.(Amicosante, Ciccozzi et
al. ; Kowada, Deshpande et al. ; Baltussen, Floyd et al. 2005; Barbieri, Wong et al. 2005;
Bachmann 2006; Dwolatzky, Trengove et al. 2006; Kominski, Varon et al. 2007; Kowada,
Takahashi et al. 2008; Rosen, Taylor et al. 2010; Shi, Hodges et al. 2010; Vassall, van Kampen et al. 2011; Fitzpatrick and Floyd 2012; Lienhardt, Raviglione et al. 2012; Mandalakas, Hesseling et al. 2012). In a recent study we compared the cost-effectiveness of direct microscopy by Ziehl Neelsen staining (AFB smear) with in house polymerase chain reaction (PCR) and with culture on the first sputum specimen collection, including staff costs, using culture and clinical evaluation as the gold standard (Scherer, Sperhacke et al. 2009). In contrast to the cost-effectiveness analysis described by van Cleef et al. in a reference ambulatory clinic in Kenya, where only culture for mycobacteria was used as the gold standard (Roos, van Cleeff et al. 1998; van Cleeff, Kivihiya- Ndugga et al. 2005). The cost-effectiveness of the AFB smear plus PCR dot-blot strategy described in recent study was similar to other strategies, when lower TB prevalence made PCR more expensive for diagnosis of PTB (Roos, van Cleeff et al. 1998; van Cleeff, Kivihiya- Ndugga et al. 2005). (Scherer et. al., 2009).

The mathematical models may be particularly useful for predicting the long term tendency of occurrence of the infection or disease. These models can simulate situations epidemiological and preventive or curative interventions beyond their theoretical impact in reducing the problem. Such predictive models properly formulated and fed with consistent data, may assist the processes of planning and management in public health. Currently several strategies have allowed the use of Multiple Logistic Regression (MLR) in the construction of predictive models. Models of decisions trees are also used for classification decision making or to provide a decision algorithm for the clinical management of infectious diseases.(Aguiar, Almeida et al. 2012)

For developing countries, the emergence of continuous technological innovation represents a double burden. The rapid diffusion of scientific and technical information that are observed now and monetary action multinational companies create a local demand for innovation by health professionals, the media and more informed portions of the population, which further strains the health care system.

Many factors limit the realization of a health technology assessment (HTA) analysis, as the lack of human resources, infrastructure or budget or due to lack of evidence or information costs.

Another obvious problem is that often decisions are based on scientific evidence coming from developed countries and often in settings where the incidence of disease differs excessively of Brazilian and Latin American scenario.

Given this scenario health managers are often between two objectives: they have to incorporate new and more costly technologies to improve the health of the population and at the same time are responsible for the financial sustainability and access equity of this in the system health.(Project 2005)

Beyond the suffering caused directly by the disease, TB is requiring significant portions of the public budget in developing countries. It is estimated that by 2015 they will be required investments around $12 billion for control of diseases such as AIDS, TB and Malaria. The increased costs involved in care and control of TB are due also to the increasing number of
cases of resistant bacteria to different types of chemotherapy. (Polansky, Dymer et al. 1968; Garcia Rodriguez, Marino Callejo et al. 1994; Weis, Foresman et al. 1999; Gomes, Soares et al. 2003; Elamin, Ibrahim et al. 2008; Kik, Olthof et al. 2009; Steffen, Menzies et al. 2010; Vassall, Seme et al. 2010; Pereira, Barreto et al. 2012)

Costs of TB diagnosis and treatment may represent a significant burden for the poor and for the health system in resource-poor countries. Costs incurred by TB patients are high in Rio de Janeiro, especially for those under DOT. The DOT strategy doubles patients’ costs and increases by fourfold the health system costs per completed treatment. The additional costs for DOT may be one of the contributing factors to the completion rates below the targeted 85% recommended by WHO (Steffen, Menzies et al. 2010).

Even in a country with a good health insurance system that covers medication and consultation costs, patients do have substantial extra expenditures. Furthermore, our patients lost on average 2.7 months of productive days. TB patients are economically vulnerable. (Kik, Olthof et al. 2009)

In Brazil, the real costs of TB are estimated or poorly known and the overall costs of TB are not perceived by governments, given the fragmentation in the involvement of the three governmental levels: local, state and national.

The purpose of this chapter is to describe the direct and indirect costs for diagnosis and treatment of Pulmonary Tuberculosis in patients infected or not by HIV, admitted to a Hospital Unit of Public Health.

### 2. Costs of health system of Brazil

In order to describe the costs of Health system of Brazil, we evaluate the costs directs of diagnosis and treatment of screening of 1000 hypothetical patients suspects of Pulmonary Tuberculosis in accordance with clinical and laboratory Brazilian recommendations for treatment (Tuberculose 2004; Conde, Melo et al. 2009).

The cost components for each clinical and laboratory procedures of screening included costs incurred by the patient, laboratory costs, drugs, consumables and equipment costs. The strategy for screening was the same recommended for Brazilian Public Health System.

Clinical, radiological and laboratory staff costs were calculated from the salary base of Rio Grande do Sul (State of Extreme South of Brazil) in 2011.

For each procedure, costs were attributed based on procedure costs of the Brazilian Public Health System.

Running costs (material costs were used for each 1000 tests evaluated) included all laboratory materials used in procedures.

All costs were expressed in US$, using an exchange rate of US$ 1 = R$ 1,72 (REAIS), the average exchange rate from 2010 to 2011. In the treatment costs, those were evaluated related to
the treatment of inpatients and outpatients. To estimate the values that are spent by the public health system of Brazil with the monitoring and control of TB in a hospital and an outpatient unit, we simulated two different scenarios:

a. TB cases diagnosed in hospital wards (hospitalized patients)

b. TB cases diagnosed in outpatient environment (outpatients).

The number of days considered to calculate the costs related to the treatment of inpatients they were considered as the same days that were spent in laboratory procedure.

It was hypothesized that the time to detect *Mycobacterium tuberculosis* in sputum culture from patients with pulmonary tuberculosis may be a better indicator for the duration of time of hospitalization (Ritchie, Harrison et al. 2007).

The time to detect *M. tuberculosis* in the culture was 30 days in this study. This cohort is the same as previous published by our group [20]. This value was used as the standard at which release from isolation could be permitted (Scherer, Sperhacke et al. 2007).

The time spent on laboratory procedure to provide access to the result of the laboratory technique was assumed to be 30 days for AFB smear plus culture. The number of days considered to calculate costs was the same as those spent on laboratory procedure. The number of days considered to calculate the cost of patient travel costs was assumed to be 2 days for AFB smear plus culture.

Total treatment included clinical officer and hospital costs, assuming cost per pill, to be US$ 0.22, using 3 pills per day, during 180 days; hospital room costs, US$ 7/day; costs with salary of clinical staff and clinical consultation, US$ 2.52 per patient and clinical nursing consultation, US$ 2.52 per patient.

Assuming that, during the treatment (6 months), in ambulatory situation, 6 AFB smear test, 6 chest radiographs, 6 consult of nurse and 2 consult of clinical were performed, we used this parameters to estimate the costs of ambulatory following the Brazilian recommendations for treatment (Tuberculose 2004).

Assuming that, during the hospitalization (30 days), 4 AFB smear tests, 4 chest radiographs, 30 nurse and physician consultations were performed, we used these parameters to estimate the costs of inpatient assistance in hospital, following the Brazilian recommendations for treatment (Tuberculose 2004; Conde, Melo et al. 2009). Staff salaries for the physician, nurse and radiologist were considered to be US$ 11,163 per year, and for the chest radiograph technician, the salary was US$ 4,988 per year. The work days were considered 20 days for all staff.

The days of admission to the hospital were considered to be the same number of days spent on each laboratory procedure. All estimated costs reflect an estimative of the public health system of Brazil expenses with the monitoring and control of TB.

The costs were expressed per 1000 suspects, according to the specific bibliographic references for economic analyses, thus, allowing the best decision for investment to be made (Petitti 2000).
Table 1A shows the costs at the health service level and Table 1B shows costs due to laboratory investment. The AFB smear plus Culture require (US$ 39,535) for equipment. Table 1C shows costs incurred by patients.

### A. Health service costs

\(a\) Microscopic and Laminar Flow Cabinets; Other equipments were not included.

\(^b\) Income loss of patients was calculated from monthly salary base of Brazil (US$207) and was based on proportional days spent by patients until access to the result of each laboratory procedure. Patient costs were estimated using the average of two visits to the laboratory for AFB smear and culture procedures for outpatients; Travel cost was considered as US$ 1.4 (one bus ticket). Food was considered as US$ 10 per meal. Base salary in Brazil was considered (US$ 10 per day /20 days of the work). For inpatients was considered just income loss; Staff costs in the laboratory were based on proportional days spent on each laboratory procedure; Costs of consumables and equipment were provided by the program as well as by the manufacturer.

Table 1. Estimative of Costs in US$ in Tuberculosis Diagnosis in Brazil

We annualized the capital cost of the equipment for 5 years, according to the literature [25]. Building costs were not included. Opportunity costs were not applicable.

\(^a\) For each procedure, costs were attributed based on procedure costs of the Brazilian Public Health System (US$ 1,4 for AFB smear and US$ 1,9 for Culture) and from CDCT/FEPPS (US$ 11,7 for PCR dot-blot), assuming investment laboratory equipment for 5 years; \(^b\) Staff salary was considered; for laboratory technician, US$2,860 per year; for Laboratory technologist, US$6,400 per year. Staff costs in the laboratory were based on proportional days spent on each laboratory procedure; Staff salary was considered for clinical physician, nurse and radiologist; US$6,400 per year; for the X-RAY technician, salary was US$2,860 per year. \(^c\) The days of admission to the hospital were considered as the same as the days spent on each laboratory procedure. The time spent on each laboratory procedure until access to the result of the laboratory technique was assumed to be 30 days for AFB smear plus Culture. Total treatment included clinical officer and hospital costs, assuming US$ 0.22 cost per pill, using 3 pills for day, during 180 days; hospital room costs, US$ 4.16/day; costs of salary of staff clinical; clinical consultation cost, US$2.52 per patient; clinical nursing consultation, US$2.52 per patient. Assuming that during the treatment of inpatients (4 months) 4 ZN and 4 chest radiograph were performed, and during the treatment of no-hospitalized patients (6 months) 6 AFB smear and 6 chest radiograph were performed, following the Brazilian recommendations for treatment (Tuberculose 2004); \(^d\) Travel was considered 2 days for AFB smear plus Culture strategy. Food and income loss for AFB smear plus Culture strategy was considered 30 days.

The health service costs analysis was based on processing 50 AFB smear slides and 14 cultures per day. AFB smear plus Culture was performed by two trained staff.

Running costs were calculated from investments required to examine 1000 smears.

Table 2. Total cost of screening for 1000 suspects. The total screening costs to AFB smear plus Culture were US$ 9,668,815.
The total cost (in US$) related to the treatment (no hospitalized patients) for AFB smear plus Culture was US$ 2,771. The cost related to the treatment of hospitalized patients, for AFB smear plus Culture strategy was US$ 4,686. The cost related to the treatment of (no hospitalized patients) and (hospitalized patients), for AFB smear plus Culture strategy was US$ 7,456.

However, in a context of advanced technologies for the diagnosis of tuberculosis, economic resources has always limited the incorporation and diffusion of new technologies produced and validated by the academy. It is a challenge for health systems worldwide, and in many cases, the cause of serious sustainability problems. (Taylor, Drummond et al. 2004; King, Griffin et al. 2006; Mason, Weatherly et al. 2007; Hughes, Tilson et al. 2009; Weatherly, Drummond et al. 2009; Shi, Hodges et al. 2010)

The decisions related to incorporation, acquisition, reimbursement or coverage of new technologies and those that determine the way in which they should be used are the most important in the health system and should be taken in general and the management of health services in particular. (Greenberg, Peterburg et al. 2005)

The health systems of different countries are diverse with respect to decisions about incorporating technologies and expectations of service users. Tough choices are faced by managers at all levels of the health system. This reality makes the TB every year, become more difficult for the system to provide the user with the most effective intervention theoretically available, depending on the pressures placed on the health system in relation to increased costs, the training of human resources, needs updating certification and regulatory instruments, and investment in physical infrastructure (Newhouse 1992)

Attempts to improve the acceptability of resource allocation decisions around new health technologies have spanned many years, fields and disciplines. Various theories of decision making have been tested and methods piloted, but, despite their availability, evidence of sustained uptake is limited. Since the challenge of determining which of many technologies to fund is one that healthcare systems have faced since their inception, an analysis of actual processes, criticisms confronted and approaches used to manage them may serve to guide the development of an ‘evidence-informed’ decision-making framework for improving the acceptability of decisions. (Stafinski, Menon et al. 2011)
