Abstract
The amorphous ribbons of Cu_{50}Zr_{40}Ni_{5}Al_{5} alloy were manufactured by rapid solidification. The ribbons were investigated by X-ray diffraction (XRD), scanning electron microscopy coupled with energy dispersive spectroscopy (SEM-EDX) and differential scanning calorimetry (DSC). The activation energy of the crystallisation in amorphous alloys was determined by Kissenger technique. The mechanical properties of the ribbons were characterized using Vickers microhardness (HV) tester. According to the XRD and SEM results, the Cu_{50}Zr_{40}Ni_{5}Al_{5} alloys have a fully amorphous structure. The EDX analysis of the ribbons showed that compositional homogeneity of the Cu_{50}Zr_{40}Ni_{5}Al_{5} alloy was fairly high. From the DSC curves of the amorphous ribbons, it was determined that glass transition temperature (T_g) is around 440–442°C and super-cooled liquid region (ΔT_x = T_x - T_g) before crystallisation is around 61–64°C. The microhardness of the as-quenched ribbons was measured about 550 HV. However, this microhardness value decreased with increasing annealing temperature and it was calculated about 465 HV after annealing temperature of 800°C.

Keywords: rapid solidification, microhardness, copper-based alloy, crystallisation, Kissenger plot

1. Introduction
Amorphous alloys, with high corrosion resistant, ultrahigh strength and soft ferromagnetic and mechanical properties, have widely been the subject of intense investigation [1–4]. These excellent properties stem from their high chemical and structural homogeneous creation. Besides, it is possible to synthesise the amorphous alloys without restriction a wide chemical composition range. Amorphous alloys are used in many applications such as defence, electric-
cal, welding, automobile and aircrafts industries. Cu-based amorphous alloys are optimal materials because of their excellent mechanical properties and high electrical and thermal conductivities for these applications [5, 6]. In addition to these applications, copper alloys are also used as the rocket nozzles, high-performance switches, the heat exchangers, the condenser tubes of ships [7, 8].

Cu-based amorphous alloys can be produced by many different techniques such as rapid solidification, mechanical alloying, vapour depositions, plasma processing and solid state reactions. In the rapid solidification method, the amorphous alloys are manufactured on thin ribbons forms, which are usually ductile and bright surface. Many Cu-based binary, ternary, quaternary and quinary alloys have been manufactured by these methods [9–15]. In this work, Cu-Zr-Ni-Al quaternary amorphous alloys are produced by rapid solidification technique at wheel surface velocities of 35 and 41 ms\(^{-1}\) as ribbons forms with very flexible. The effects of the wheel surface velocities and different annealing process on mechanical and microstructural properties of produced ribbons are systematically investigated. Therefore, it has been revealed the amorphous nature of Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) ribbon alloys in order to contribute the continuously improving Cu-based alloys in industry.

2. Methods and materials

An ingot of the Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) (at.\%) alloy was prepared by arc melting the mixtures of the pure elements, Cu (99.7%), Zr (99.9%), Ni (99.5%) and Al (99.99%) in a titanium-gettered argon atmosphere. From this alloy, ribbon materials of approximately 75 μm thickness and 5 mm in width were manufactured by a single-roller Edmund Bühler melt spinner at wheel surface velocities of 35 and 41 ms\(^{-1}\). The structure of the ribbon samples was examined by XRD using a Philips XPert powder diffractometer with Cu-Kα radiation generated at 40 kV and 30 mA. The transformations temperatures and heat effects during transformations were examined by Perkin-Elmer Sapphire DSC unit under inert gas atmosphere using continuous heating mode with the heating rate of 40 K min\(^{-1}\). Moreover, the DSC analysis was carried out for the melt-spun ribbon at wheel speed of 35 ms\(^{-1}\) using continuous heating mode with the heating rates of 5–40 K min\(^{-1}\). The cross section of the melt-spun ribbons was studied by Zeiss Evo LS10 SEM and SEM-EDX after conventional metallographic preparation. The ribbons were annealed for 30 min at different temperatures under vacuum/inert gas atmosphere. These temperature values are 300, 580, 680 and 800°C. The annealed ribbons were investigated by XRD from surface, SEM from cross-section with the same conditions used for as-quenched ribbons. The Vickers microhardness measurements of the as-quenched and subsequently annealed ribbons were performed using a Shimadzu HMV-2 by an applied load of 0.98 N with a dwell time of 10 s at ten different locations.

3. Results and Discussion

Figure 1 shows the X-ray diffraction patterns of the rapidly solidified Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) ribbons produced at wheel surface velocities of 35 and 41 ms\(^{-1}\). As shown in Figure 1, the XRD patterns
exhibit the broad maxima characteristic which is feature of amorphous materials without the evidence of any crystalline peaks. This means that the surface velocities of 35 and 41 ms\(^{-1}\) are optimal to synthesize Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) alloy as fully amorphous structure.

**Figure 1.** XRD pattern of the melt-spun Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) ribbons prepared at wheel speeds of 35 and 41 ms\(^{-1}\) as-quenched.

DSC traces of amorphous Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) alloys at wheel speeds of 35 and 41 ms\(^{-1}\) at a heating rate of 40 K min\(^{-1}\) display distinct and an obvious glass transition temperature, \(T_g\), before crystallisation, as shown in **Figure 2**. From the DSC curves, it is seen a wide super-cooled liquid temperature range followed by a pronounced exothermic reaction for both ribbon alloys. **Table 1** summarises the characteristic temperatures which are glass transition temperature (\(T_g\)), crystallisation temperature (\(T_x\)), super-cooled liquid region (\(\Delta T_x (\Delta T_x = T_x - T_g)\)), and peak temperature (\(T_p\)) of the Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) alloy. According to the **Table 1**, \(T_x\), \(\Delta T_x\), and \(T_p\) increase while \(T_g\) decreases with increasing melt-spun wheel surface velocity.

**Figure 2.** The DSC curves of the Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) ribbon alloys at wheel speeds of 35 and 41 ms\(^{-1}\) obtained during heating at a heating rate of 40 K min\(^{-1}\).

Figure 3 exhibits the DSC curves at 5, 10, 20 and 40 K min$^{-1}$ of the ribbon alloy which are manufactured at wheel speeds of 35 ms$^{-1}$. The obtained peak temperature values, $T_p$, $T_x$, $T_g$ and the super-cooled liquid region ($\Delta T_x$) from Figure 3 are presented Table 2. As can be seen Table 2, $T_p$, $T_x$, $T_g$ and $\Delta T_x$ values are moved to higher temperatures with increasing heating rate. It is attributed the heating rate which are depended on the parameters of crystallisation and glass transition during continuous heating [7, 16]. Therefore, this case reveals the significant of the kinetic aspects of the glass transition for glassy alloys [17].

The activation energy \( (E) \) for glass transition or crystallisation is commonly estimated by the Kissinger [18] equation. The Eq. (1) is given below. To calculate activation energy of the amorphous alloys with this equation, it is necessary to use data from different heating rates of the alloy

\[
\ln\left(\frac{\phi}{T^2}\right) = -\frac{E}{RT} + A
\]

where \( T \) is the specific temperature, glass transition temperature \( (T_g) \), crystallisation temperature \( (T_x) \), or peak temperature \( (T_p) \), \( \phi \) is the heating rate, \( R \) is the gas constant \((8.314 \text{ J/mol K})\), \( E \) is the activation energy, \( A \) is a constant. By plotting \( \ln(\phi/T^2) \) versus \( 1/(RT) \), nearly a straight line is obtained. From the slope of this straight line, the activation energies \( E_g \), \( E_x \) or \( E_p \) are calculated using the certain peak temperatures \( (T_g, T_x, T_p) \). Figure 4 shows the Kissenger plots of Cu\(_{50}\)Zr\(_{40}\)Ni\(_5\)Al\(_5\) ribbon alloy produced at wheel speed of 35 ms\(^{-1}\). From the Kissenger plots, the activation energies \( E_g \), \( E_x \) and \( E_p \) are determined 421.35 (±12), 432.26 (±9) and 403.05 (±6) kJ/mol, respectively. These values are very high compared with previous studies whose activation energies are \( E_g = 393 \), \( E_p = 381 \) kJ/mol for Cu\(_{50}\)Zr\(_{40}\)Ni\(_5\)Al\(_5\) alloy [7], \( E_g = 357 \), \( E_x = 297 \), \( E_p = 289 \) kJ/mol for Cu\(_{52.5}\)Zr\(_{11.5}\)Ti\(_{30}\)Ni\(_6\) [19] and \( E_g = 377 \), \( E_x = 307 \), \( E_p = 340 \) kJ/mol for Cu\(_{50}\)Zr\(_{40}\)Ag\(_7\)Al\(_{3}\) alloy [20]. On the other hand, it is also possible to mention that the amorphous Cu\(_{50}\)Zr\(_{40}\)Ni\(_5\)Al\(_5\) alloy has very high thermodynamic stability with \( E_x = 432.26 \) kJ/mol value compared with previous works.

![Figure 4. Kissinger plots of the amorphous Cu\(_{50}\)Zr\(_{40}\)Ni\(_5\)Al\(_5\) alloy produced at wheel speed of 35 ms\(^{-1}\).](http://dx.doi.org/10.5772/63513)
The annealing of the amorphous alloys is a significant process to characterise their crystallisation behaviour. Thus, it might be revealed that the amorphous structure transforms into what kind of crystalline phases with increasing annealing temperature. For this purpose, the melt-spun ribbon of Cu$_{50}$Zr$_{40}$Ni$_{5}$Al$_{5}$ alloy synthesised at wheel speed of 35 ms$^{-1}$ was annealed in the temperature range of 300–800°C for 30 min. Figure 5 shows the XRD patterns of Cu$_{50}$Zr$_{40}$Ni$_{5}$Al$_{5}$ alloy after annealing. According to Figure 5, before exothermic reaction, the XRD pattern of Cu$_{50}$Zr$_{40}$Ni$_{5}$Al$_{5}$ alloy with annealed of 300°C exhibits fully an amorphous structure. After the annealing temperature of 580°C, intermetallic phases with sharp diffraction peaks have been obtained from the amorphous matrix and fully crystallisation of the amorphous phase. This result is in good agreement with crystallisation peak in DSC traces which is above 503°C. The obtained phases in the XRD spectrum were marked by symbols and indexed as cubic-AlCu$_2$Zr with lattice parameters, $a = b = c = 6215$ Å, orthorhombic-Cu$_{10}$Zr$_7$ with lattice parameters, $a = 9347$; $b = 9322$; $c = 12,976$ Å, tetragonal-Zr$_2$Cu with lattice parameters, $a = 3220$; $b = 3220$; $c = 11,183$ Å and f.c.c-Cu with lattice parameters, $a = b = c = 3615$ Å. These phases were also observed in previous works after a similar annealing process for Cu-based amorphous alloys [7, 20–22]. Number of the crystalline peaks which belongs to AlCu$_2$Zr, Cu$_{10}$Zr$_7$, Zr$_2$Cu and Cu phases was increased by increasing annealing temperature (800°C), as shown in Figure 5.

![Figure 5](image_url)

**Figure 5.** XRD pattern of the melt-spun ribbon of Cu$_{50}$Zr$_{40}$Ni$_{5}$Al$_{5}$ alloy manufactured at a wheel speed of 35 ms$^{-1}$ and annealed in the temperature range of 200–800°C for 30 min.

In addition to XRD patterns of annealed ribbons, typical SEM micrographs from cross section of the amorphous Cu$_{50}$Zr$_{40}$Ni$_{5}$Al$_{5}$ alloy prepared at a wheel speed of 35 ms$^{-1}$ as well as annealing ribbons at 300, 580, 680 and 800°C are shown in Figure 6. In Figure 6a, b, the microstructure
with featureless morphology of unannealed and annealed at 300°C ribbons are exhibited. This featureless morphology is a typical characteristic of the amorphous materials. In previous works, similar SEM images taken surface of amorphous structured materials were reported [7, 23, 24]. These micrographs are in accord with the XRD spectrums which exhibit fully amorphous features unannealed (Figure 1) and annealed at 300°C ribbons (Figure 5). As can be seen obviously in Figure 6c–e, with increasing annealing temperature (580, 680, 800°C), the microstructure of Cu_{50}Zr_{40}Ni_{5}Al_{5} ribbon alloys changes and transforms into irregularly shaped features which is a characteristic of crystalline structures. These crystalline structures belong to AlCu_{2}Zr, Cu_{10}Zr_{7}, Zr_{2}Cu or Cu phases obtained by XRD patterns (Figure 5).

Figure 6. Typical SEM images from the cross section of the melt-spun ribbon of Cu_{50}Zr_{40}Ni_{5}Al_{5} alloy prepared at a wheel speed of 35 m s^{-1}. (a) As-quenched and annealed at the temperatures, (b) 300°C, (c) 580°C, (d) 680°C, and (e) 800°C.

The compositional homogeneity of the amorphous Cu_{50}Zr_{40}Ni_{5}Al_{5} ribbons was by measured EDX in order to confirm initially intended composition values. The EDX analysis illustrates mean values of element concentrations of Cu_{50}Zr_{40}Ni_{5}Al_{5} alloy produced at a wheel speed of
35 ms\(^{-1}\) in Figure 7. As can be seen obviously from the EDX results, the peaks in the spectrum belong to Cu, Zr, Ni and Al elements. As shown in Figure 7, the average chemical composition of the ribbon alloy is in good agreement with the chemical composition values of Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) alloy.

In order to determine the influence of annealing on the microhardness of the Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) ribbon alloys which are as-quenched and annealed at different temperatures such as 200, 275, 400, 500, 600 and 800°C, Vickers HV measurements were analysed. The following Eq. (2) was used for these measurements [25]

\[
HV = \frac{2P\sin(\theta / 2)}{d^2} = \frac{1.8544(P)}{d^2}
\]

where \(P\) is the indentation force, \(d\) is the mean diagonal length, and 1.854 is the geometrical factor for the diamond pyramid. Figure 8 shows the variation of microhardness values with increasing annealing temperature for Cu\(_{50}\)Zr\(_{40}\)Ni\(_{5}\)Al\(_{5}\) alloy prepared at wheel speed of 35 ms\(^{-1}\). As shown in Figure 8, the hardness values decrease with increasing annealing temperature. In previous works, this decline of the hardness values with the annealing temperature is generally reported for Cu-based amorphous alloys [7, 26–31]. The microhardness of as-quenched ribbon was calculated 550 HV, while it was determined 532–470 HV for annealed ribbons in the range of 200–500°C (Figure 8). At the temperature range of 500–800°C, the
microhardness values of the Cu₅₀Zr₄₀Ni₅Al₅ alloy were not changed distinctly and it was determined as approximately 465 HV. Thus, it can easily be concluded that the highest microhardness value (550 HV) of the Cu₅₀Zr₄₀Ni₅Al₅ alloy was measured for as-quenched ribbon alloy.

Figure 8. The change in Vickers microhardness values for Cu₅₀Zr₄₀Ni₅Al₅ alloy prepared by the wheel speed of 35 ms⁻¹ with annealing temperatures.

4. Conclusions

1. The metallic glass Cu₅₀Zr₄₀Ni₅Al₅ alloys were successfully produced by rapid solidification technique at wheel speeds of 35 and 41 ms⁻¹.

2. DSC traces of the Cu₅₀Zr₄₀Ni₅Al₅ alloys showed similar distinct glass transition, T_g which are around 440–442°C. The ribbon alloys exhibited also wide super-cooled liquid regions, ΔT_x which are 61–64°C.

3. The activation energies of E_p, E_x and E_p for Cu₅₀Zr₄₀Ni₅Al₅ alloy prepared at wheel speed of 35 ms⁻¹ were determined 421.35 (±12), 432.26 (±9) and 403.05 (±6) kJ/mol, respectively.

4. The intermetallic AlCu₂Zr, Cu₁₀Zr₇, Zr₅Cu and Cu phases in the microstructure of Cu₅₀Zr₄₀Ni₅Al₅ alloy were observed after annealing temperature of 800°C.
5. The compositional homogeneity of Cu$_{50}$Zr$_{40}$Ni$_5$Al$_5$ as-quenched ribbons was most correctly confirmed by EDX.

6. The microhardness value of Cu$_{50}$Zr$_{40}$Ni$_5$Al$_5$ alloy was calculated approximately 550 HV for unannealed ribbons. However, it decreased with increasing annealing temperatures and was measured about 465 HV after annealing temperature of 800°C.
