The Pharmacological Effects of Herbs on Catecholamine Signaling

Nobuyuki Yanagihara, Xiaojia Li, Yumiko Toyohira, Noriaki Satoh, Hui Shao, Yasuhiro Nozaki, Shin Ishikane, Fumi Takahashi, Ryo Okada, Hideyuki Kobayashi, Masato Tsutsui and Taizo Kita

Abstract

Herbs have many biologically and pharmacologically active compounds such as flavonoids and stilbenes. They have been used in remedies for various disorders. Here we review the effects of herbs on catecholamine synthesis and secretion in cultured bovine adrenal medullary cells. Ikarisoside A (1.0–100 μM), a flavonol glycoside, inhibited the catecholamine secretion induced by acetylcholine (0.3 mM). This inhibition was associated with the suppression of \[^{22}\text{Na}^+\] and \[^{45}\text{Ca}^{2+}\] influx induced by acetylcholine. The ethanol extract (0.0003–0.005%) of matsufushi (extract of pine nodules) inhibited the catecholamine secretion induced by acetylcholine. SJ-2, one of the stilbene compounds isolated from matsufushi, inhibited acetylcholine-induced catecholamine secretion. Matsufushi extract and SJ-2 reversibly inhibited acetylcholine-induced \[^{14}\text{C}\text{-catecholamine} \] synthesis from \[^{14}\text{C}\text{-tyrosine}\]. Matsufushi extract and SJ-2 reversibly inhibited acetylcholine-induced \[^{14}\text{C}\text{-catecholamine} \] synthesis from \[^{14}\text{C}\text{-tyrosine}\]. These findings indicate that ikarisoside A, matsufushi (or SJ-2), and sweet tea inhibit the catecholamine secretion and synthesis induced by acetylcholine in cultured bovine adrenal medullary cells and probably in sympathetic neurons.

Keywords: adrenal medullary cells, catecholamine secretion, ikarisoside A, matsufushi, sweet tea

1. Introduction

Since herbs have many biologically and pharmacologically active compounds such as flavonoids and stilbenes, they have been used in remedies for various disorders. A high dietary intake of herbs has become a focus of research because of herbs’ potential to reduce the risks of diseases such as hypertension, coronary heart disease, diabetes, and cancers [1, 2]. Flavonoids are a group of plant secondary metabolites with variable phenolic structures, and they are found in plants, fruits, vegetables, roots, stems, flowers, wine, and tea [3, 4]. Over 5000 individual flavonoids have been reported [5], and 6 principal groups of flavonoids
(flavones, flavonols, flavanones, flavanols, isoflavones, and anthocyanidins) are relatively common in human diets [1]. Polyphenol stilbenes have attracted scientific attention. For example, resveratrol (trans-3,4',5-trihydroxy-stilbene) is a natural phytoestrogen found in grapes, berries, and red wine [6, 7] that was reported to be implicated in the beneficial effect of red wine, i.e., the lower incidence of coronary artery disease in certain populations such as the French and the Greeks, despite diets rich in saturated fat and a rate of high smoking, which has been dubbed the “French paradox” [8].

In the human body, the most abundant catecholamines are adrenaline, noradrenaline, and dopamine, all of which are produced from phenylalanine and/or tyrosine. Catecholamines are biosynthesized mainly in the adrenal medulla, the postganglionic fibers of the sympathetic nervous system, and the central nervous system [2, 9, 10]. Catecholamines play very important roles in aspects of the cardiovascular system such as heart rate and blood pressure, blood glucose levels, and the general functions of the central and peripheral sympathetic nervous system [9].

Adrenal medullary cells derived from embryonic neural crests are functionally homologous to sympathetic postganglionic neurons [2, 10]. Our research demonstrated that in cultured bovine adrenal medullary cells, at least three distinct types of ionic channels participate in catecholamine secretion, including nicotinic acetylcholine receptor (nAChR)-ion channels, voltage-dependent Na⁺ channels, and voltage-dependent Ca²⁺ channels [2, 11]. In these cells, the Na⁺ influx induced by acetylcholine (ACh) via nAChR-ion channels or by veratridine via voltage-dependent Na⁺ channels is a prerequisite for Ca²⁺ influx via the activation of voltage-dependent Ca²⁺ channels and subsequent catecholamine secretion; in contrast, high K⁺ directly gates voltage-dependent Ca²⁺ channels to increase the Ca²⁺ influx without increasing the Na⁺ influx [10, 11] (Figure 1). ACh-induced Ca²⁺ influx is also a prerequisite for the stimulation of catecholamine synthesis associated with the activation of tyrosine hydroxylase [2, 12–15]. The mechanisms underlying the stimulation of catecholamine synthesis and secretion mediated by these ion channels in adrenal medullary cells are thought to be similar to those of

---

The mechanism underlying the regulation of catecholamine synthesis, secretion, and reuptake in bovine adrenal medullary cells.
noradrenaline in the sympathetic neurons and brain noradrenergic neurons [2]. Thus, adrenal medullary cells have provided a good model for the detailed analysis of antipsychotic [16], cardiovascular [17], and analgesic [18] drugs that act on catecholamine synthesis, secretion, and reuptake [2].

We have demonstrated the effects of several flavonoids and polyphenol stilbenes on catecholamine synthesis and secretion. For example, the treatment of bovine adrenal medullary cells with daidzein (an isoflavone derived from soy beans) stimulated basal catecholamine synthesis but inhibited the catecholamine synthesis and secretion induced by ACh [2, 19]. Genistein (another isoflavone in soy beans) but not daidzein stimulated the function of noradrenaline transporter in a human neuroblastoma cell line, SK-N-SH cells [2, 20]. Nobiletin (a compound of polymethoxy flavone in citrus fruits) stimulated the basal synthesis and secretion of catecholamines, but it suppressed both the ACh-induced synthesis of catecholamines and ACh-induced secretion of catecholamines [2, 21]. Resveratrol also inhibited the catecholamine synthesis and secretion induced by ACh [2, 22].

The present review summarizes our recent and current studies of the pharmacological effects of herbs and their components, i.e., ikarisoside A (a flavonol glycoside); matsufushi (extract of pine nodules), one of matsufushi’s stilbene components (SJ-2); and sweet tea on the catecholamine signaling induced by ACh in cultured bovine adrenal medullary cells and on ACh-induced Na⁺ current in Xenopus oocytes expressing α3β4 nAChRs.

2. Inhibitory effects of ikarisoside A, but not its aglycon, on the catecholamine secretion and synthesis induced by ACh

Ikarisoside A is a natural flavonol glycoside derived from plants of the genus Epimedium, which have been used in traditional Chinese medicine as tonics, antirheumatics, and aphrodisiacs [10, 23, 24], and is used as a tonic supplement in Japan. Ikarisoside A has antioxidant and anti-inflammatory effects [23] and anti-osteoporosis effects [10, 25]. Icariin, another flavonoid in the genus Epimedium, has an anti-stress effect in the forced swimming test in mice [26].

We observed that ikarisoside A (1–100 μM) concentration dependently inhibited the secretion of catecholamines induced by ACh (0.3 mM) (Figure 2A), but not the secretion of catecholamines induced by veratridine and 56 mM K⁺ [10]. Ikarisoside A also suppressed the 22Na⁺ influx and 45Ca²⁺ influx induced by ACh in a concentration-dependent manner similar to that of catecholamine secretion (Figure 2B, C) [10]. Ikarisoside A is a flavonol glycoside with one rhamnose at the 3 position in the chemical structure. The aglycon of ikarisoside A is 3,5,7-trihydroxy-2-(4-hydroxyphenyl)-8-(3-methylbut-2-enyl)-4H-chromen-4-one (Figure 3A).

It is interesting to note that the aglycon of ikarisoside A had little effect on catecholamine secretion induced by ACh (0.3 mM) (Figure 3B), suggesting that the rhamnose moiety at the 3 position of ikarisoside A is essential to inhibit the function of nAChR-ion channels [10]. Ikarisoside A (1.0–100 or 10–100 μM) inhibited ACh (0.3 mM)-induced [14C]-catecholamine synthesis from [14C]-tyrosine and tyrosine hydroxylase activity [10].

3. Inhibitory effects of matsufushi and its stilbene component, SJ-2, on the catecholamine synthesis and secretion induced by ACh

Pine nodules of Pinus tabulaeformis or Pinus massoniana are formed by pine bark proliferation at places on the trunk or limbs that have undergone damage, either
Figure 2.
Effects of ikarisoside A on ACh-induced catecholamine secretion (A), $^{45}\text{Ca}^{2+}$ influx (B), and $^{22}\text{Na}^+$ influx (C).

(A) Cultured bovine adrenal medullary cells (10$^6$/well) were stimulated with ACh (300 μM) in the presence or absence of ikarisoside A (0.3–100 μM) for 10 min at 37°C. Catecholamine secretion is expressed as a percentage of the total catecholamines in the cells. (B and C) Cells (4 $\times$ 10$^6$/well) are stimulated with ACh (300 μM) and 1.5 μCi of $^{45}\text{CaCl}_2$ (B) or $^{22}\text{NaCl}$ (C) in the presence or absence of ikarisoside A (0.3–100 μM) for 5 min at 37°C. $^{45}\text{Ca}^{2+}$ influx and $^{22}\text{Na}^+$ influx were expressed as nmol/4 $\times$ 10$^6$ cells. Data are means ± SEM from three separate experiments carried out in triplicate. **P < 0.01 and ***P < 0.001 vs. ACh alone (by one-way ANOVA with Dunnett’s multiple comparison post hoc test) (cited from [25]).

Figure 3.
Structures of ikarisoside A and its aglycon (A) and the effect of aglycon of ikarisoside A on the catecholamine secretion induced by ACh (0.3 mM) (B). (A) Chemical structures of ikarisoside A and its aglycon (3,5,7-trihydroxy-2-(4-hydroxyphenyl)-8-(3-methylbut-2-enyl)-4H-chromen-4-one). (B) Cells (10$^6$/well) were incubated with or without aglycon of ikarisoside A (1–100 μM) and ACh (300 μM) for 10 min at 37°C. Catecholamine secretion is expressed as a percentage of the total. Data are means ± SEM from three separate experiments carried out in triplicate (cited from [25]).

by pests or physical injury [27]. The effective curative components in pine nodule extract (matsufushi) have been used as an analgesic for joint pain, rheumatism, neuralgia, dysmenorrhea, and other complaints in traditional Chinese medicine [27–29]. Matsufushi is used as a healthy supplement in Japan.

Matsufushi ethanol extract (0.0003–0.005%) concentration dependently inhibited the catecholamine secretion and $^{45}\text{Ca}^{2+}$ influx induced by ACh (0.3 mM) and veratridine (0.1 mM), but not 56 mM K$^+$ in cultured bovine adrenal medullary cells [27]. Four compounds (SJ-2, SL-3, SJ-4, and SJ-16) were isolated from matsufushi extract (Figure 4). SJ-2, a phenol stilbene, and the mixture of four compounds (Mix4; SJ-2, SJ-3, SJ-4, and SJ-16), but not each of the other separate compounds, inhibited the catecholamine secretion (Figure 5) and $^{45}\text{Ca}^{2+}$ influx [27] induced by ACh (0.3 mM). In Xenopus oocytes

Figure 4. Chemical structures of SJ-2, SJ-3, SJ-4, and SJ-16 (cited from [28]).

Figure 5. Effects of SJ-2, SJ-3, SJ-4, SJ-16, and their mixture (Mix4) on catecholamine secretion induced by ACh in cultured bovine adrenal medullary cells. The cells (10$^6$/well) were incubated with or without SJ-2 (10 μM), SJ-3 (10 μM), SJ-4 (10 μM), C-16 (10 μM), and their mixture (Mix 4) (10 μM) for 10 min at 37°C. Catecholamine secretion is expressed as a percentage of the total catecholamines in the cells. Data are means ± SEM from three separate experiments carried out in triplicate. *P < 0.001 vs. ACh alone. Rha: rhamnose (cited from [28]).
expressed with $\alpha3\beta4$ nAChRs, matsufushi extract and SJ-2 reversibly inhibited ACh ($0.2 \text{ mM}$)-induced Na$^+$ currents (Figure 6A, C). Matsufushi extract ($0.0001\%$) and SJ-2 ($10 \mu\text{M}$) suppressed the currents induced by the EC$_{50}$ ($0.2 \text{ mM}$) of ACh, and the inhibitory effects were reversible. Concentration-response curve for the inhibitory effects of matsufushi extract (B) and SJ-2 (D) on ACh-induced currents. The peak current amplitude in the presence of matsufushi extract and SJ-2 was normalized to that of the control, and the effects are expressed as percentages of the control. Data are presented as means ± SEM from four separate experiments carried out in triplicate. $^\star P < 0.05$ and $^\star\star\star P < 0.001$ vs. the control (cited from [28]).

Figure 6. Effects of ethanol extract of matsufushi and SJ-2 on inward currents induced by ACh in Xenopus oocytes expressing rat $\alpha3\beta4$ nAChRs. Representative traces from a single Xenopus oocyte are shown. The currents of matsufushi-treated (A) and SJ-2-treated (C) oocytes were recorded for 20 min after recording of the control currents, and the washout currents were obtained for 20 min after matsufushi extract and SJ-2 treatment. Matsufushi extract ($0.0001\%$) and SJ-2 ($10 \mu\text{M}$) suppressed the currents induced by the EC$_{50}$ ($0.2 \text{ mM}$) of ACh, and the inhibitory effects were reversible. Concentration-response curve for the inhibitory effects of matsufushi extract (B) and SJ-2 (D) on ACh-induced currents. The peak current amplitude in the presence of matsufushi extract and SJ-2 was normalized to that of the control, and the effects are expressed as percentages of the control. Data are presented as means ± SEM from four separate experiments carried out in triplicate. $^\star P < 0.05$ and $^\star\star\star P < 0.001$ vs. the control (cited from [28]).

4. Effects of the extract of sweet tea on catecholamine secretion and synthesis in adrenal medullary cells

Sweet tea is the processed leaves of Hydrangea macrophylla var. thunbergii Makino (hydrangeae dulcis folium), which is listed in the Japanese Pharmacopeia XV and used as a sweetening agent for diabetic patients. It also has antimicrobial and anti-allergic
effects [30, 31]. Sweet tea is used as a healthy tea in Japan. There is, however, little evidence regarding sweet tea’s effects on the sympathetic nervous system activity. We investigated the effects of the extract of sweet tea on adrenal medullary cell function. A dry powder of sweet tea prepared from fermented leaves of hydrangea dulcis folium was solubilized at 5.0 mg/ml and extracted at 90°C for 60 min. The extract of sweet tea (1.0 mg/ml) slightly increased the basal secretion of catecholamines (Figure 7A), whereas it suppressed the catecholamine secretion induced by ACh (0.3 mM) in a concentration-dependent manner (300–1000 μg/ml) (Figure 7A). In addition, the extract of sweet tea (300–1000 μg/ml) inhibited basal and ACh (0.3 mM)-induced 14C-catecholamine synthesis from 14C-tyrosine, respectively (Figure 7B). Sweet tea at concentrations of 3 mg/ml is usually used for drinking.

5. The insight of pharmacological potential of herbs in the catecholamine signaling induced by ACh in adrenal medulla

Adrenal medullary cells are derived from the embryonic neural crest and share many physiological and pharmacological properties with postganglionic sympathetic
neurons [2]. The stimulation of AChRs in these cells increases the synthesis of catecholamines and causes the secretion of catecholamines into the systemic circulation [2, 11, 14]. In adrenal medullary cells, the Na\(^+\) influx induced by ACh via nAChR-ion channels is a prerequisite for Ca\(^{2+}\) influx via the activation of voltage-dependent Ca\(^{2+}\) channels and the subsequent catecholamine secretion and synthesis; in contrast, high K\(^+\) directly gates voltage-dependent Ca\(^{2+}\) channels to increase \(^{45}\)Ca\(^{2+}\) influx [2, 11] (Figure 1).

As we noted, ikarisoside A and matsufushi (or SJ-2) inhibited the catecholamine secretion induced by ACh, but not the secretion induced by 56 mM K\(^+\) [10, 27]. In addition, ikarisoside A [10] and matsufushi [27] or SJ-2 [27] suppressed the Na\(^+\) current induced by ACh in Xenopus oocytes expressing \(\alpha3\beta4\) nAChRs. These results suggest that the herbs and their components used as described herein inhibit the ACh-induced secretion and synthesis of catecholamines via a suppression of Na\(^+\) influx mediated through nAChRs in adrenal medullary cells [10, 27].

It is well known that catecholamines have important roles in the regulation of normal function in the central and peripheral sympathetic nervous systems as a neurotransmitter but also in the adrenal medulla as an endocrine hormone [10]. Strong and prolonged stress causes massive amounts of catecholamine release, which can lead to cardiovascular diseases (such as hypertension, coronary heart disease, heart failure, and atherosclerosis), and such stress also suppresses the immune system to induce some cancers [2, 9, 10]. Indeed, chronic heart failure is associated with the activation of the sympathetic nervous system as manifested by an increased circulating level of noradrenaline and increased regional activity of the sympathetic nervous system [2, 32]. It was reported that the stress hormone adrenaline stimulates \(\beta2\)-adrenoceptors to activate the Gs-protein-dependent protein kinase A and the \(\beta\)-arrestin-1-mediated signaling pathway, which, in turn, suppresses p53 levels and triggers DNA damage [2, 33]. On the basis of these previous and present results, it appears that the herbs and their components such as ikarisoside A, matsufushi...
(or SJ-2), and sweet tea suppress the induction of a hyperactive catecholamine system induced by strong stress or emotional excitation (Figure 8).

6. Future perspective

Although the in vitro effects of the herbs and herb components described herein have been well clarified using cultured bovine adrenal medullary cells and *Xenopus* oocytes, the in vivo results are not yet clear. To confirm the pharmacological effects of these herbs on the catecholamine system, further in vivo studies of the effects of the administration of herbs to animals or humans are needed [2, 27]. We observed a disturbance of the autonomic nervous balance in women with climacteric symptoms measured by a power spectral analysis of heart rate variability [34]. Using this assay method, we will examine the effect of herbs on the autonomic nervous activity under some stress conditions.

7. Concluding remarks

We have reviewed the evidence that herbs and their components such as ikariso-side A, matsufushi (or SJ-2), and sweet tea inhibit the catecholamine synthesis and secretion induced by ACh in cultured bovine adrenal medullary cells and summarized them in Table 1. These findings may provide new insights into the pharmacological potentials of herbs on the hyperactive catecholamine system induced by stress.
