Heat Transfer and Thermal Radiation at a General Three-Dimensional in a Nanofluid through a Porous Medium

Gamal M. Abdel-Rahman and Faiza M.N. El-fayez

Abstract

In this chapter, the magnetohydrodynamic effects on heat transfer and thermal radiation at a stagnation point flowing in a nanofluid containing different types of nanoparticles namely, copper (Cu), alumina (Al₂O₃) and titania (TiO₂) through a porous medium have been investigated numerically. By using appropriate transformation for velocity and temperature into a set of non-linear coupled ordinary differential equations which are solved numerically. Numerical results are presented for velocity and temperature profiles for different parameters of the problem. Also, the effects of the pertinent parameters on the skin friction and the heat fluxes are obtained and discussed numerically and illustrated graphically.

Keywords: nanofluid, MHD, porous medium, thermal radiation, heat transfer

1. Introduction

Nanofluids have novel properties that make them potentially useful in many applications. They exhibit enhanced thermal conductivity and the convective heat transfer coefficient compared to the base fluid [1], so the nanofluids transfer heat at a higher rate than ordinary fluids (for example, water) which allows for more efficient heating or cooling while reducing energy consumption. Since nanofluid consists of very small sized solid particles, therefore in low solid concentration it is reasonable to consider nanofluid as a single-phase flow [2].

The term “nanofluid” refers to a liquid containing a suspension of submicronic solid particles (nanoparticles). This interest is generated by a variety of applications, ranging from laser-assisted drug delivery to electronic chip cooling. The term was coined by Choi [3]. The characteristic feature of nanofluids is thermal conductivity enhancement, a phenomenon observed by Masuda et al. [4]. This phenomenon suggests the possibility of using nanofluids in advanced nuclear system [5].

In recent years, numerous investigations have been conducted on the magnetohydrodynamic (MHD) flows and heat transfer because of its important applications in metallurgical industry, such as the cooling of continuous strips and filaments, drawn through a quiescent fluid and the purification of molten metals from non-metallic inclusions. It is known that the properties of the final product depend considerably on the rate of cooling during the manufacturing processes. The rate of cooling can be
controlled by drawing the strips in an electrically conducting fluid subject to a mag-
netic field, so that a final product of desired characteristics can be achieved [6]. One

can solve this problem by using solid particles as an additive suspended into the base
fluid as Choi [3] did, who first utilized and used fluids suspended by nanometer-sized
solid particles. The resulting mixture referred to as a nanofluid possesses a substan-
tially larger thermal conductivity compared to that of the traditional fluids [7]. These
suspended nanoparticles can change the transport and thermal properties of the base
fluid [8]. Therefore, by mixing the nanoparticles in the fluid, thermal conductivity of
the fluid increases and the heat transfer capability improves.

The flow and heat transfer characteristics at a stagnation point, for both two-
dimensional and axisymmetric, have been studied extensively in the literature [9].
These studies have been motivated by the fundamental nature of the boundary layer
flows near such points by the exact applicability of similar solutions and by their
relevance to the leading edge and nose regions of bodies in high speed flows. These
two cases of two-dimensional and axisymmetric flows can be recognized as special
cases of more general stagnation point flows. Both two-dimensional and axisymmetric
flows were extended to three-dimensional by Howarth [10]. Bhattacharyya and Gupta
[11] studied the flow and heat transfer in an incompressible viscous and electrically
conducting fluid near a three-dimensional stagnation point of a body permeated by a
uniform magnetic field. Analysis of such flows is very important in both theory and in
practice. From a theoretical point of view, flows of this type are fundamental in fluid
mechanics and forced convective heat transfer. On the other hand, from a practical
point of view, these flows have applications in many manufacturing processes in
industry such as the boundary layer along material handling conveyers, the aerody-
namic extrusion of plastic sheet and petrochemical industries.

It is worth mentioning that the nanofluid model proposed by Buongiorno [12]
was very recently used by Nield and Kuznetsov [13], Kuznetsov and Nield [14] and
Bachok et al. [15] in their papers. Different from the above model.

The aim of the present chapter is to study the Magnetohydrodynamic effects on
heat transfer and thermal radiation in an incompressible viscous fluid near the
three-dimensional stagnation point of a body that is placed in a water based
nanofluid through a porous medium containing different types of nanoparticles:
copper (Cu), alumina (Al₂O₃) and titania (TiO₂). Numerical results are presented
for velocity and temperature profiles for different parameters of the problem.

2. Mathematical analysis

Consider a flow of an electrically conducting fluid with heat transfer flow at a
stagnation point of an incompressible viscous fluid past a body that is placed in a
nanofluid of ambient uniform temperature \( T_\infty \) through a porous medium in the
presence of radiation has been considered, where the body surface is kept at a
constant temperature \( T_w \). The stagnation point is located at the origin \( o \) of the
Cartesian coordinate system \( oxyz \). It was shown by Howarth [10] that the inviscid
irrational flow near \( o \) has the velocity components

\[
 u_e(x) = ax, \quad v_e(y) = by 
\]

with the constants \( a > 0 \) and \( b \geq 0 \) or \( b \leq 0 \).

The MHD body forces \( \mathbf{J} \times \mathbf{B} \) the Maxwell’s equations:

\[
 \text{div} \mathbf{B} = 0, \quad \text{Curl} \mathbf{B} = \mu_0 \mathbf{J} \quad \text{and} \quad \text{div} \mathbf{E} = 0 
\]
where \( J \) is the electric current density, \( B = \mathbf{B} + d \) is the total magnetic field, \( \mu_f \) is the magnetic permeability and \( d \) is the induced magnetic field. The magnetic Reynolds number of the flow is taken to be small, so that the flow induction distortion of the applied magnetic field can be neglected as in the case with most of conducting fluids. The magnetic body force \( \mathbf{J} \times \mathbf{B} \) takes the form \( \sigma \mathbf{V} \times \mathbf{B} \), therefore, \( \sigma \mathbf{V} \times \mathbf{B} = -\sigma \mathbf{B}^2 \mathbf{V} \), where \( \mathbf{V} = (u, v, w) \) and \( \mathbf{B} = (0, 0, B) \). The Lorentz force (MHD body force) has two components:

\[
F_x = -\sigma B^2 u, \quad F_y = -\sigma B^2 v.
\]

We now make the standard boundary-layer approximation, based on a scale analysis, and write the governing equations (see [6, 11]):

\[
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} + \frac{\partial w}{\partial z} = 0, \tag{2}
\]

\[
\frac{u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} = a^2 x + \frac{\mu_{nf}}{\rho_{nf}} \frac{\partial^2 u}{\partial z^2} - \frac{\sigma B^2}{\rho_{nf}} u, \tag{3}
\]

\[
\frac{u}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} = b^2 x + \frac{\mu_{nf}}{\rho_{nf}} \frac{\partial^2 v}{\partial z^2} - \frac{\sigma B^2}{\rho_{nf}} v, \tag{4}
\]

\[
\frac{u}{\partial x} + v \frac{\partial T}{\partial y} + w \frac{\partial T}{\partial z} = \alpha_{nf} \frac{\partial^2 T}{\partial z^2} - \frac{1}{\rho_{nf} c_p} \frac{\partial q_r}{\partial z}, \tag{5}
\]

Subject to the boundary conditions

\[
u = v = w = 0, \quad T = T_w \quad \text{at} \quad z = 0
\]

\[
u \to u_0(x), \quad v \to v_0(y), \quad T \to T_{\infty} \quad \text{as} \quad z \to \infty. \tag{6}
\]

Here \( \mu_{nf} \) the viscosity of the nanofluid, \( \alpha_{nf} \) the thermal diffusivity of the nanofluid and \( \rho_{nf} \) the density of the nanofluid, which are given by

\[
\mu_{nf} = \frac{\mu_f}{(1 - \varphi)^{5/2}}, \quad \alpha_{nf} = \frac{k_{nf}}{\rho_{nf} c_p}, \quad \rho_{nf} = (1 - \varphi)\rho_f + \varphi \rho_s
\]

\[
(\rho C_p)_{nf} = (1 - \varphi)(\rho C_p)_f + \varphi (\rho C_p)_s
\]

\[
k_{nf} \equiv \frac{k_f + 2k_s}{k_f + 2k_s} - 2\varphi (k_f - k_s)
\]

\[
k_f \equiv \frac{k_f}{k_f + 2k_s} + \varphi (k_f - k_s)
\]

where \( q_r \) is the energy flux which is relative to a frame moving with the nanofluid velocity. Using the Rosseland approximation (Rashed [16]), the radiative heat flux \( q_r \) could be expressed by

\[
q_r = -k_1 \frac{\partial T^4}{\partial z} \tag{8}
\]

where \( k_1 = 4\sigma^*/3k^* \) is the nanofluid thermal conductivity.

Assuming that the temperature difference within the flow is sufficiently small such that \( T^4 \) could be approached as the linear function of temperature,

\[
T^4 \approx 4T_{\infty}^3 T - 3T_{\infty}^4 \tag{9}
\]
Further, we look for a solution of Eqs. (2)–(5) of the form

\[ u = ax^f(\eta), \quad v = by^g(\eta), \quad w = -\sqrt{ax^f[f + cg]}, \]

\[ \theta(\eta) = \frac{(T - T_\infty)}{(T_w - T_\infty)}, \quad \eta = \sqrt{a/\nu^2} \tag{10} \]

where \( c = b/a \) is the ratio of the gradient of velocities in the \( y \)- and \( x \)-directions, and primes denote differentiation with respect to \( \eta \). Substituting Eqs. (8)–(10) in Eqs. (2)–(5), we obtain the following nonlinear ordinary differential equations:

\[ \left( \frac{1}{(1 - \phi)^{5/2} \left( 1 - \rho_1 \phi \right)} \right) \left[ f^{||} - M(1 - \phi)^{5/2} f^\prime - S f^{||} \right] + (f + cg)f^{\prime\prime} - f^{||} + 1 = 0, \tag{11} \]

\[ \left( \frac{1}{(1 - \phi)^{5/2} \left( 1 - \rho_1 \phi \right)} \right) \left[ g^{||} - M(1 - \phi)^{5/2} g^\prime - S g^{||} \right] + (f + cg)g^{\prime\prime} + c(1 - g^{||}) = 0, \tag{12} \]

\[ \left( \frac{(k_{nf} / k_f) + Q}{P_f \left( 1 - \phi \left( 1 - \rho p_f / \rho p_1 \phi \right) \right)} \right) \phi^{||} + (f + cg)\phi^\prime = 0, \tag{13} \]

With the appropriate boundary conditions:

\[ f^\prime(0) = 0, g^\prime(0) = 0, f(0) = -c g(0), \theta(0) = 1, \]

\[ f^\prime(\infty) = 1, g^\prime(\infty) = 1, \theta(\infty) = 0. \tag{14} \]

where the prime denotes a partial differentiation with respect to \( \eta \), \( M = \sigma B^2 / \nu p_f \) is the Magnetic field parameter, \( S = \nu_f / \nu k_T \) is the Porous medium parameter and \( Q = 4k_T T_\infty^3 \) is the Thermal radiation parameter.

There is no loss of generality in the requirement that \( |a| \geq |b| \) with \( a > 0 \). Clearly \( b = 0 \) corresponds to the plane stagnation point flow case, while \( b = a \) is the axisymmetric case. The case \( 0 < c < 1 \) displays the nodal stagnation point of attachment (\( b > 0 \)), while \( -1 < c < 0 \) displays the saddle points of attachment (\( b < 0 \)) \([5]\).

3. Skin-friction coefficient and Nusselt number

The parameters of engineering interest for the present problem are the local skin-friction coefficients \( C_{fx} \) and \( C_{fy} \), along the \( x \)- and \( y \)-directions, respectively, and the local Nusselt number \( Nu_x \), which are defined as

\[ C_{fx} = \frac{\tau_{ux}}{ax \nu_T u^2_w}, \quad C_{fy} = \frac{\tau_{uy}}{by \nu_T u^2_w}, \quad Nu_x = \frac{u^2_w q_w}{ak_T (T_w - T_\infty)}, \tag{15} \]

where \( \tau_{ux} \) and \( \tau_{uy} \) are the surface shear stresses along the \( x \)- and \( y \)-directions, respectively, and \( q_w \) is the surface heat flux, which are given by

\[ \tau_{ux} = \mu_{nf} \left( \frac{\partial u}{\partial z} \right)_{z=0}, \quad \tau_{uy} = \mu_{nf} \left( \frac{\partial v}{\partial z} \right)_{z=0}, \quad q_w = -k_{nf} \left( \frac{\partial T}{\partial z} \right)_{z=0} \tag{16} \]
Using Eqs. (10), (15), and (16), we obtain

\[
\text{Re}_x^{1/2} C_{fx} = \frac{1}{(1-\phi)^{1/3}} f^{''/}(0), \quad \text{Re}_x^{1/2} C_{fy} = \frac{1}{(1-\phi)^{5/3}} g^{''/}(0),
\]

\[
\text{Re}_x^{-1/2} Nu_x = \frac{k_{nf}}{k_f} \theta^{''}(0)
\]

(17)

where \(\text{Re}_x = u_0^4/(\nu f)\) is the local Reynolds number.

4. Results and discussion

Numerical solutions to the nonlinear ordinary differential Eqs. (11)–(14) were obtained using the modified fourth order Runge-Kutta method along with Nachtsheim-Swigert shooting technique [17]. In order to gain physical insight, the velocity and the temperature profiles have been discussed by assigning numerical values to the parameter, encountered in the problem which the numerical results are tabulated and displayed with the graphical illustrations Figure 1. We find the missing slopes \(f^{''/}(0), g^{''/}(0)\) and \(-\theta^{''}(0)\) for some values of the governing parameters, namely the nanoparticle volume fraction \(\phi\) and the ratio of the gradient of velocities in the i- and x-directions \(c\), where \(0 < c < 1\) displays the nodal stagnation point of attachment and \(-1 < c < 0\) displays the saddle points of attachment. Three types of nanoparticles were considered, namely, copper (Cu), alumina (\(\text{Al}_2\text{O}_3\)) and titania (\(\text{TiO}_2\)). Following Oztop and Abu-Nada [18], the value of the Prandtl number \(P_r\) is taken as 6.2 (for water) and the volume fraction of nanoparticles is from 0 to 0.2 \(0 \leq \phi \leq 0.2\) in which \(\phi\) corresponds to the regular Newtonian fluid. The numerical results are summarized in Figures 2–6. It is worth mentioning that we have used data related to the thermophysical properties of the fluid and nanoparticles as listed in Table 1 [18] to compute each case of the nanofluid.

Figures 2, 3 and 5a–c, display the velocity \(f^{''/}(\eta), g^{''/}(\eta)\) and the temperature \(\theta^{''}(\eta)\) profiles under the different parameters of the problem as magnetic field parameter, porous medium parameter and nanoparticle parameter. It is observed that the velocity profile decreases, while the temperature profile increases with the increase in each of magnetic field parameter, porous medium parameter and nanoparticle parameter. The effects of the nanoparticle volume fractions on the velocity and the temperature profiles are shown in Figure 4a–c, respectively. It is observed that the

Figure 1.
Effect of nanoparticle volume fractions on (a) the velocity profile \(f^{''/}(\eta)\), (b) the velocity profile \(g^{''/}(\eta)\) and (c) the temperature profile \(\theta^{''}(\eta)\) at \(c = 0.5\) and \(-0.5\) for copper-water nanofluid.
velocity and the temperature profiles increase with the increase of the nanoparticle volume fractions. The effects of thermal radiation parameter on the temperature profile are shown in Figure 6; also, we found that the temperature profiles increase with the increase of thermal radiation parameters. i.e. as expected, since the effect of thermal radiation is to decrease the rate of energy transport to the fluid.

Table 1.
Thermophysical properties of fluid and nanoparticles [18].
From Table 2, the numerical values of the skin-friction and the local Nusselt number are given in Table 2. For an increase in the magnetic field parameter $M$, we observe that the skin-friction coefficient along $x$- and $y$-directions and the local Nusselt number decrease when $c = 0.5$, but at $c = -0.5$, the skin-friction coefficient along $x$-direction and the local Nusselt number decrease, while the skin-friction coefficient along $y$-direction increases. While, with an increase in the porous medium parameter $S$, we observe that the skin-friction coefficient and the local Nusselt number decrease when $c = -0.5$ and $c = -0.5$.

With an increase in nanoparticle volume fractions $\phi$, we observe that the skin-friction coefficient increases and the local Nusselt number increases when $c = 0.5$, but at $c = -0.5$, the skin-friction coefficient along $y$-direction and the local Nusselt number decrease, while the skin-friction coefficient along $x$-direction increases. While, with an increase in the thermal radiation parameter $Q$, we observe that the local Nusselt number decreases when $c = -0.5$ and $c = -0.5$.

5. Conclusions

In the present chapter, the magnetohydrodynamic effects on heat transfer and thermal radiation at a stagnation point flowing in a nanofluid containing different types of nanoparticles namely, copper (Cu), alumina ($\text{Al}_2\text{O}_3$) and titania ($\text{TiO}_2$) through a porous medium have been investigated numerically. By using appropriate transformation for velocity and temperature into a set of non-linear coupled ordinary differential equations which are solved numerically, the governing equations were:

1. With the increasing values of the magnetic field parameter, porous medium parameter and nanoparticle parameter, it is observed that the velocity profile decreases, while the temperature profile increases.
2. The velocity and the temperature profiles increase with the increase of the nanoparticle volume fractions.

3. For the effects of thermal radiation parameter on the temperature profile, we found that the temperature profiles increase with the increase of thermal radiation parameters.

4. For an increase in the magnetic field parameter $M$, we observe that the skin-friction coefficient along $x$- and $y$-directions and the local Nusselt number decrease when $c = 0.5$, but at $c = -0.5$, the skin-friction coefficient along $x$-direction and the local Nusselt number decrease, while the skin-friction coefficient along $y$-direction increases.

5. About the effects of the porous medium parameter $S$, we observe that the skin-friction coefficient and the local Nusselt number decrease when $c = 0.5$ and $c = -0.5$.

6. The local Nusselt number decreases when $c = -0.5$ and $c = -0.5$, with the increase of the thermal radiation parameter $Q$.

**Nomenclature**

- $a$: constant
- $B$: magnetic field
- $b$: constant
- $c$: the ratio of the gradient of velocities in the $y$- and $x$-directions
- $C_{fx}, C_{fy}$: skin friction in the $y$- and $x$-directions
- $d$: the induced magnetic field
- $k_{nf}$: the thermal conductivity of the nanofluid
- $k_f$: the thermal conductivities of the fluid
- $k_s$: the thermal conductivities of the solid fractions
- $k_1$: the nanofluid thermal conductivity
- $k^*$: mean absorption coefficient
- $Nu_s$: Nusselt number
- $M$: magnetic field parameter
- $Q$: thermal radiation parameter
- $q_r$: the energy flux which is relative to a frame moving with the nanofluid velocity
- $q_{so}$: the surface heat flux
- $T$: temperature distribution
- $T_w$: constant temperature
- $T_\infty$: ambient uniform temperature
- $S$: porous medium parameter
- $Re_s$: the local Reynolds number
- $u$: velocity in the $x$-direction
- $v$: velocity in the $y$-direction
- $w$: velocity in the $z$-direction
- $x$: horizontal distance
- $y$: vertical distance
- $z$: normal distance

**Greek symbols**

- $\alpha_{nf}$: the thermal diffusivity of the nanofluid
η similarity variable
θ dimensionless temperature distribution
μf the viscosity of the fluid
μnf the viscosity of the nanofluid
ρf the densities of the fluid
ρs density of the solid fractions
ρnf density of the nanofluid
νf kinematic viscosity of the fluid
(ρ Cp)f the heat capacity of the fluid
(ρ Cp)s the heat capacity of the solid fractions
κ the permeability of the porous medium
σ electrical conductivity
σ* Stephan-Boltzmann constant
τwx, τwy the surface shear stresses along the x- and y-directions
φ nanoparticle volume fraction
Subscripts
w, ∞ conditions at the surface and in the free stream
