Chapter

L-arginine Metabolism in the Infection with Trypanosoma cruzi

Laila Gutiérrez-Kobeh and Arturo A. Wilkins-Rodríguez

Abstract

Trypanosoma cruzi is the causal agent of Chagas disease that affects 6–7 million people around the world, principally in Latin America. This disease is characterized for the presence of an acute phase in which the host immune response plays a central role in the elimination of the parasite. If the parasite is not efficiently eliminated, patients can remain asymptomatic or develop a chronic infection. One of the cells that are primarily infected with this intracellular parasite is macrophages (Mφ). Mφ present a wide array of activation states with classically activated macrophages (CAMφ) and alternatively activated macrophages (AAMφ) in the other. One of the most important differences between these two activation states is the presence of the inducible nitric oxide synthase (iNOS or NOS2) in CAMφ and arginase 1 (Arg-1) in AAMφ; both enzymes share the same substrate, L-arginine, and are reciprocally regulated by the action of Th1 cytokines in the case of NOS2 and Th2 cytokines in the case of Arg-1. The activation of CAMφ permits the production of nitric oxide (NO), highly trypanotoxic, while the activation of AAMφ allows the synthesis of polyamines, necessary for parasite duplication. L-arginine is a very important metabolite situated in the center between the elimination and perpetuation of T. cruzi.

Keywords: arginase-1, L-arginine, inducible nitric oxide synthase, macrophages, trypanosoma cruzi

1. Introduction

Trypanosoma cruzi is the causal agent of Chagas disease that affects 6–7 million people around the world, mainly in Latin America [1], although in the last years it has also become a potential public health problem in developed countries due to the constant migrations with cases reported in the USA, Canada, Europe, Japan, and Australia [2].

This intracellular obligate parasite enters the human host in the form of metacyclic promastigotes that are released from the triatomine feces during the blood meal, through damaged skin or mucosae. Alternatively, infection can occur through other routes such as oral, congenital, blood transfusions, or organ transplants. After entering the host, trypomastigotes are phagocytized mainly by macrophages, where they transform to amastigotes, the intracellular form that has the ability to replicate. In order to evade the host immune response and ensure its persistence inside macrophages, Trypanosoma has developed multiple strategies. One of these has as a target L-arginine metabolism. Macrophages can eliminate amastigotes or permit their survival depending on the balance of two inducible enzymes nitric
oxido synthase (iNOS or NOS2) and arginase-1 (Arg-1) that share the same sub-
strate: L-arginine. During the activation of macrophages in the context known as
classical activation, L-arginine is metabolized by iNOS giving rise to the production
of nitric oxide (NO), one important trypanotoxic agent that permits these cells to
destroy the parasite. On the other hand, during the activation of macrophages in the
context known as alternative activation, L-arginine is metabolized by Arg-1 giving
rise to the production of polyamines that favor multiplication and persistence of
Trypanosoma in these cells. Thus, L-arginine is situated as a frontier between the
elimination and survival of Trypanosoma in macrophages, and its metabolism is a
determinant factor for the evolution of the disease.

2. Phases of the infection with Trypanosoma cruzi

The infection with T. cruzi presents an acute phase that is auto-limiting and can
go unnoticed in many infected individuals. During this phase, parasites actively
duplicate in different cells and tissues such as macrophages; muscular cells of
smooth, striated, and cardiac muscles; adipocytes; and cells of the central nervous
system [3]. While some patients succumb during the acute phase of the disease, the
development of an adaptive immune generally permits the control of infection with
T. cruzi. If the parasite is not completely eradicated, individuals remain infected
for life, and a dynamic equilibrium is established with the parasite that results in
different clinical outcomes. In this way, while many individuals chronically infected
remain in an asymptomatic intermediate phase, a significant proportion (30–35%)
of patients develop cardiac or digestive manifestations that can drive them to
congestive cardiac failure, arrhythmias, and eventually death or develop colon or
esophageal megasystomades. All of these are irreversible pathologic changes that
occur even though the presence of the parasite is scarce. One experimental model
that recapitulates chagasic myocarditis is present in infected mice for long periods
with different T. cruzi strains that develop chronic lesion in the myocardium [4, 5].

3. Generalities of L-arginine

L-arginine is one of the most versatile amino acids at the metabolic level. Besides
serving as a precursor for protein synthesis, it is also a precursor of multiple
compounds of great biologic importance such as urea, nitric oxide, polyamines,
L-proline, glutamate, creatinine, and agmatine (Figure 1) [6, 7].

In adult mammals, L-arginine is a nonessential amino acid; nevertheless, during
childhood and certain physiologic or pathologic conditions (e.g., pregnancy, sepsis,
trauma, catabolic stress, intestinal or renal damage), it is considered as a semi-
essential amino acid or conditioned nonessential, due to the fact that its consumption
exceeds the capacity of being synthesized by the organism and has to be supplied
exogenously [8–10]. In mammals, the provision of L-arginine depends on its procure-
ment through the protein diet, endogenous synthesis (de novo synthesis), and its
release during the process of protein replacement (Figure 1) [6]. Approximately 40%
of the L-arginine that is obtained from the protein diet is catabolized in the intestine
before entering the circulation [11]. In the absence of the contribution by the protein
diet, approximately 80% of the L-arginine that enters the circulation derives from
the protein replacement, and the remaining percentage is obtained through the
de novo synthesis [11]. L-arginine metabolism occurs basically in the liver and kidney;
nevertheless, other tissues and cells also possess the required enzymes to metabolize
it, including some cells of the immune response [12]. Regarding last point, it is
interesting to note that a complete urea cycle has been described in macrophages [13]. Although only two enzymes directly involved in l-arginine synthesis have been identified (arginine succinate synthetase and arginine succinate lyase that are the third and fourth enzymes of the urea cycle), four enzymes utilize this amino acid as substrate: arginine decarboxylase, arginine/glycine aminotransferase, different isoforms of arginase (Arg), and the different isoforms of the nitric oxide synthases (NOS), the last two being the most studied and characterized [12]. In mammals two arginase isoforms exist, Arg-1 and Arg-2, that catalyze the same reaction but differ in cellular expression and subcellular localization. Arg-1 is cytosolic and is highly expressed in the liver and some cells of the immune response. Compared to Arg-1, Arg-2 is mitochondrial and is expressed in a great variety of peripheral tissues, mainly in the kidney, prostate, small intestine, and mammary glands during lactation [14]. Regarding NOS, this enzyme is present in three isoforms: neuronal NOS (nNOS or NOS1), inducible nitric oxide synthase (iNOS or NOS2), and endothelial NOS (eNOS or NOS3). NOS 1 is expressed in specific neurons of the central nervous system (CNS), and NOS3 is mostly expressed in endothelial cells [15]. NOS 2 is not usually expressed in cells, but its expression can be induced by bacterial lipopolysaccharide, cytokines, and other agents. Although primarily identified in macrophages, the expression of this enzyme can be stimulated in almost any cell or tissue, provided that the appropriate inducing agents are present [16].

4. L-arginine metabolism in the immune response: special emphasis in macrophages

In the immune response, l-arginine metabolism through NOS2 and Arg-1 has a pivotal role in the regulation of the effector capabilities of macrophages, dendritic cells, and neutrophils [17–20] during infectious processes caused by a great variety of microorganisms: different species of Mycobacterium, Leishmania, Trypanosoma, Schistosoma, and Salmonella, among others [21, 22].

L-arginine metabolism in the immune response acquired great relevance with the discovery that murine macrophages express both NOS2 and Arg-1 and that their expression is reciprocally regulated by the action of Th1/proinflammatory cytokines (e.g., IFN-γ and TNF-α) and Th2/anti-inflammatory (e.g., IL-4, IL-10, and IL-13) that determine the activation state of macrophages [19, 23–27]. Th1
cytokines activate macrophages in a classical way (CAMΦ) and induce the expression and function of NOS2, while Th2 cytokines activate macrophages in an alternative way (AAMΦ) and induce the expression and function of Arg-1.

NOS2 or iNOS is an oxide-reductase responsible for the synthesis of L-citrulline and nitric oxide (NO•) from L-arginine in the presence of NADPH and oxygen. This reaction occurs through two successive reactions: the monoxygenation of L-arginine that drives to the production of the intermediary N\(^\omega\)-OH-L-arginine (NOHA) and the subsequent hydrolysis of this last compound, thus producing L-citrulline and NO• (Figure 2). NOS2 generates both NO• and superoxide (O\(^2\)\(^-\)) that together react to form the radical peroxynitrite (ONOO\(^-\)) [28]. This last compound has been identified as a reactive species derived both from oxygen and nitrogen (RONS) that constitutes the principal cytostatic or cytotoxic mechanism of CAMΦ to fight the infections generated by virus, bacteria, fungi, and protozoan parasites [20, 23, 26, 29].

5. Immune response to Trypanosoma cruzi

Inside the mammalian host, macrophages represent an important site for the duplication of T. cruzi. One of the most important mechanisms in the protective immunity against T. cruzi is the activation of macrophages in order to achieve the elimination of parasites (Figure 3). CAMΦ are able eliminate T. cruzi thanks to

DOI: http://dx.doi.org/10.5772/intechopen.85010

NOS2 and RONS that kill intracellular parasites by the modification of structural properties of *T. cruzi* molecules. On the other hand, the different forms of AAMϕ present high levels of mannose receptor (MR) and an overregulation of Arginase 1 [30]. Arg-1 hydrolyzes l-arginine in urea and l-ornithine; the latter is the principal intracellular source for the synthesis of polyamines and trypanothione. Polyamines are small cationic molecules required for cellular proliferation and macrophage homeostatic processes, besides being vital for the intracellular growth of *Trypanosoma* [19, 31]. Both inducible enzymes share l-arginine as substrate, and the expression and function of both enzymes are reciprocally regulated by the action of Th1 and Th2 cytokines. Thus, l-arginine is situated as a frontier between the elimination and survival of *Trypanosoma* in host cells, and its metabolism is a determinant factor in the evolution of the disease.

In response to the defense mechanisms of the host, parasites have developed several strategies in order to escape host immune response and take advantage of some host’s molecules. In this way, parasites must reduce the production of toxic molecules, including nitric oxide and its derivatives, that are synthesized by the immune system, in particular by macrophages [32–34]. In addition, internalized parasites of different *T. cruzi* strains are able to escape from the parasitophorous vacuole of resident macrophages [35], a strategy that utilizes a variety of molecules with antioxidant properties [36, 37]. Nevertheless, as the infection progresses, the evasion strategies displayed by *T. cruzi* are widely surpassed by the development of a humoral specific immune response and the activation of macrophages by IFN-γ and other cytokines. As has been previously mentioned, the infection with *T. cruzi* can have an acute or a chronic phase. One of the possible causes of the passage from one phase to another is the fact that the effector immune response against the parasite is insufficient or inappropriate due to a deficient activation of the specific immune response or an excessive regulation of this response.

6. Role of Arg-1 in the infection with *Trypanosoma*

The induction of Arg-1 in macrophages promotes the infection of parasites of the genus *Trypanosoma* by providing nutrients derived from polyamines, since *Trypanosoma* parasites cannot generate their own source of ornithine through the activity of a functional arginase [38, 39]. The increase in arginase activity counteracts the host’s immune response and favors parasite growth. It has been shown that in African trypanosomiasis caused by *Trypanosoma gambiense*, there is an increase in the serum level of Arg-1 that returns to basal values after the treatment.
Similarly, in experimental murine trypanosomiasis caused by *Trypanosoma brucei*, macrophage Arg-1 activity represents a disease susceptibility marker [41]. In *T. brucei* Arg-1 activity is induced by excretion/secretion factors, particularly TbKHC1, kinesin H chain, and has been identified as an inductor factor of Arg-1 [38]. Other studies have demonstrated that the addition of an Arg-1 inhibitor reduces parasite growth, which is restored with l-ornithine supplementation. The essential requirement of l-ornithine is related with the absence of a functional arginase in *Trypanosoma* [39], which results in a dependence toward host’s arginase for the synthesis of polyamines and trypanothione, which are essential for parasite survival, growth, and differentiation [42]. The difluoromethylornithine, structural analog of l-ornithine, has been used alone or in combination with nifurtimox as an effective drug against African trypanosomiasis [43]. Nevertheless, its administration is difficult and requires large amounts of i.v. injected fluids, which limits its use in remote areas. Thus, it is of utmost importance to find easier ways to select polyamine synthesis as a target against *Trypanosoma*. Alternatively, inhibitors of the route that conducts to arginase activity might reduce parasite loads in infected animals.

7. Conclusion

*Trypanosoma cruzi* is the causal agent of Chagas disease that affects 6–8 million people primarily in Latin America. It is an intracellular parasite that infects a variety of cells, among which macrophages are a very important target and thus transcendental for the immune response against the parasite. Macrophages can traverse through a gradient of stages of activation with classically activated macrophages in one end and alternatively activated macrophages in the other. These two phases of activation are characterized by the expression of two enzymes that are reciprocally regulated and share the same substrate: l-arginine. Classically activated macrophages express iNOS of NOS2 that is induced by Th1 cytokines and catalyze the conversion of L-arginine to L-citrulline and NO. Contrarily, alternatively activated macrophages express Arg-1 that is induced by Th2 cytokines. Thus, l-arginine metabolism is in the center of *Trypanosoma* elimination of survival. The better knowledge of this route during the different stages of *Trypanosoma* infection is of great importance for the better comprehension of disease progression and design of drugs.
